Packet Switching on L2, v4.11

# Why Packet Switching on LAN?

# LAN was primarily designed for shared media

- but too many clients cause performance problems
  - · higher probability for collisions in case of Ethernet

# Partitioning of a network may be needed

- to achieve load balance
- for error limitation
- because of security reasons
- to deal with technological limitations
  - · geographical expansion, number of clients
- for using resources of distant networks (remote networking)

© 2008, D.I. Manfred Lindner

Packet Switching on L2, v4.11

2

# **Bridge / Router**

# network partitioning

- can be done by packet switches (OSI relay stations on L3)
  - · already well known store and forward principle of WAN world

# bridge

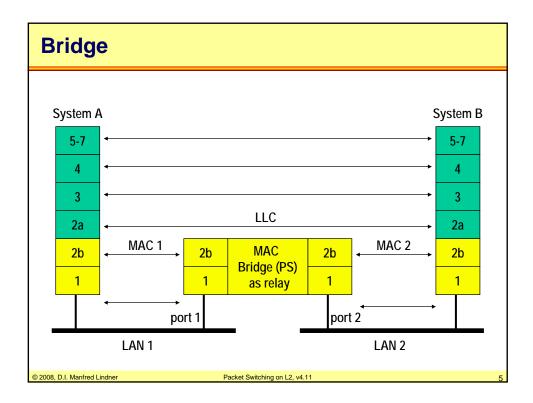

- packet switch implemented on OSI layer 2
- forwarding based on unstructured MAC addresses
- signposts stored in MAC bridging table ( = routing table of L2 packet switch)
- above OSI Layer 2b bridges are transparent for all higher layer protocols (LLC and above)

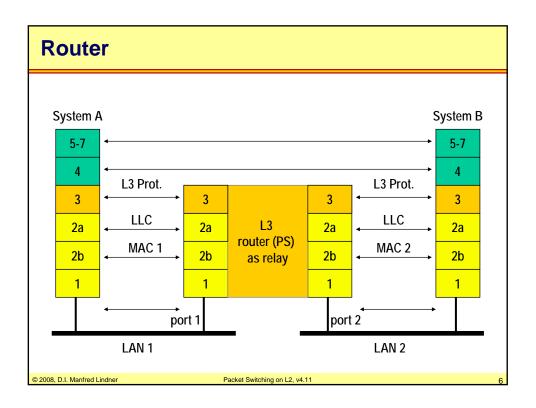

### router

- packet switch implemented on OSI layer 3
- forwarding based on structured L3 addresses
- end system must speak the corresponding L3 "language"

2008, D.I. Manfred Lindner

Packet Switching on L2, v4.11

# **Bridging Methods**

- Transparent Bridging (Ethernet world)
  - easy for end systems
  - more complex transferring-decisions (compared to source route bridging) have to be done by such a bridge
  - dedicated hardware
  - today's L2 switch technology (Ethernet switch) is actually a <u>fast</u> transparent bridge only
- Source Routing Bridging (Token Ring world, IBM)
  - more overhead for end systems (path finding)
  - source route bridges are less complex
  - could be done e.g. by a PC with two network cards
  - not further covered in this lecture

© 2008, D.I. Manfred Lindner

Packet Switching on L2, v4.1

# **Agenda**

- Introduction

© 2008, D.I. Manfred Lindner

Packet Switching on L2, v4.11

# **Transparent Bridging**

1

- bridge is invisible for end systems
  - LAN 1 and LAN 2 appear to the end systems like one single, logical, big LAN -> transparent
- bridge uses layer 2 MAC-addresses
  - to decide if a given frame must be a forwarded or not
    - · destination-address of a frame is used for this
- MAC-addresses of all stations are registered in a bridging table
  - either statically done by administrator
  - or dynamically done by a self-learning mechanism
    - source-address of a frame is used for this

© 2008, D.I. Manfred Lindner

Packet Switching on L2, v4.1

0

# **Transparent Bridging**

2

- in case of a dynamic bridging table
  - an aging mechanism allows for changes of MAC addresses in the network
    - may caused either by change of network card or by location change of end system
    - if an already registered MAC address is not seen within e.g. 5
      minutes as source address of a frame the bridging table entry is
      deleted
- because of the transparency
  - such a bridge must receive and process every frame on a LAN
- flow control
  - originally not done between end systems and bridges

© 2008, D.I. Manfred Lindner

Packet Switching on L2, v4.11

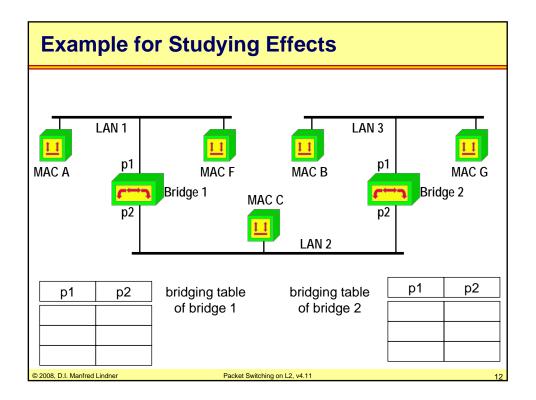

# **Transparent Bridging**

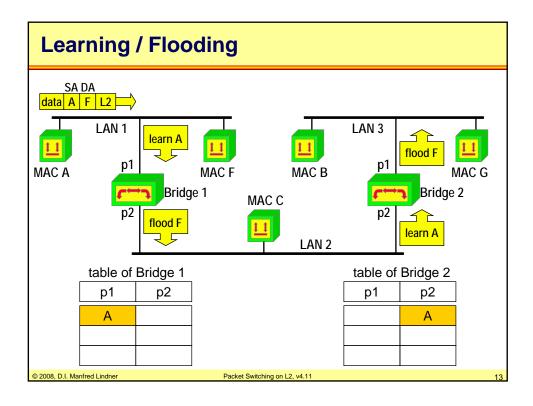

3

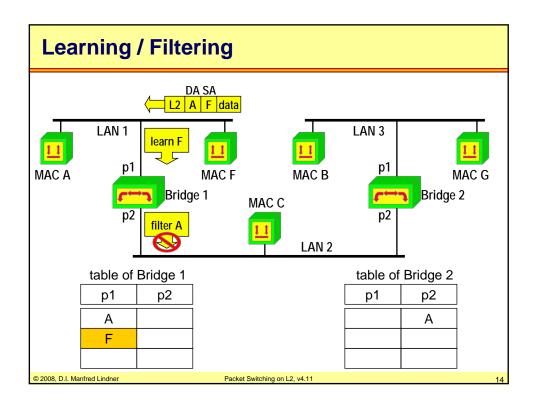

- destination address of a frame is used for table look up which enables a simple decision:
  - <u>filtering</u>: frame will be rejected if destination's home is on the LAN segment of the receiving port
  - forwarding: a duplicate of the frame will be forwarded to the appropriate port if destination's home is registered in the table of another port
  - <u>flooding:</u> during learning time; frame will be forwarded to all other ports (multiport-bridge) if there is no entry in the table (unknown destination)
- frames with broadcast/multicast-address
  - are always forwarded to all other ports

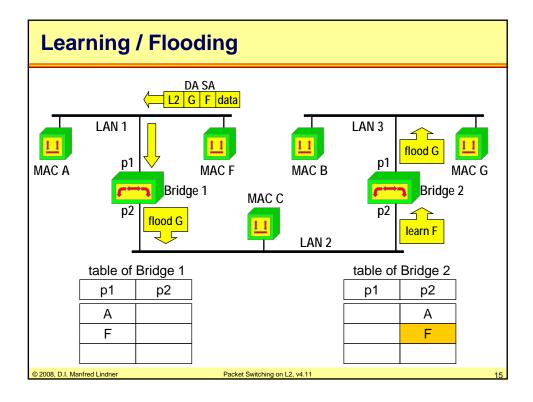

© 2008, D.I. Manfred Lindner

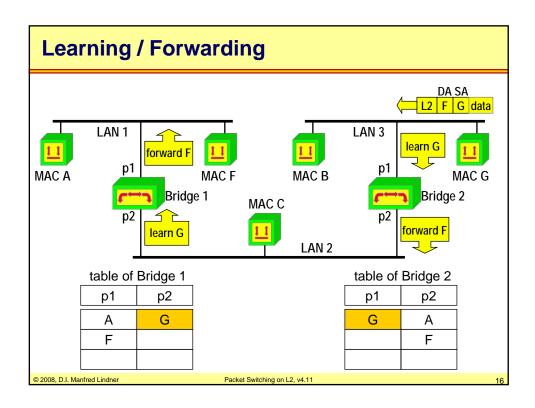

Packet Switching on L2, v4.11

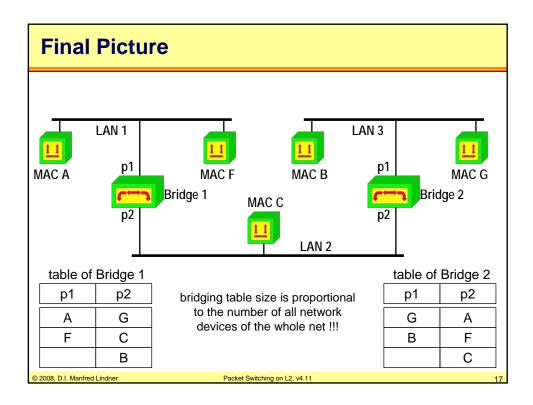

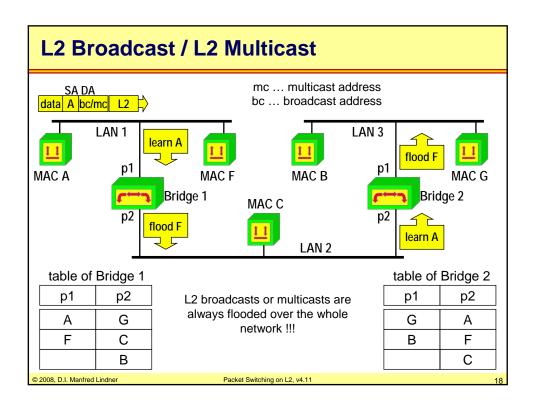

# **Collision Domain versus Broadcast Domain**

# bridge separates LAN into

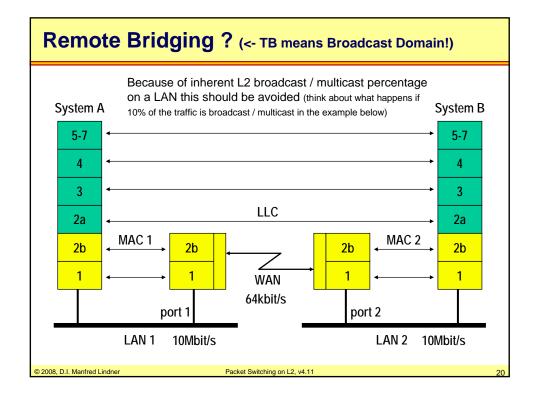

- multiple <u>collision domains</u>
- a collision on one LAN segment will not be seen on other LAN segments
- reason: store and forward behavior of bridge
- note: a repeater can't do that

# but a bridged network is still

- one broadcast domain
- broadcast frames are always flooded
- reason: bridged LAN is still seen as one logical LAN by end systems, bridges are <u>transparent</u> for them

© 2008, D.I. Manfred Lindner

Packet Switching on L2, v4.11

# **Remote Bridging**

- relay function of local bridge
  - is split in two half-bridges
- coupling of the half-bridges
  - via WAN-connection
- high amount of broadcast on a LAN
  - mismatch of data rates
  - slow WAN-connection can cause a buffer overflow in the bridge
  - therefore transparent bridging over WAN or any other
     Ethernet tunnelling technique should be avoided

© 2008, D.I. Manfred Lindne

Packet Switching on L2, v4.1

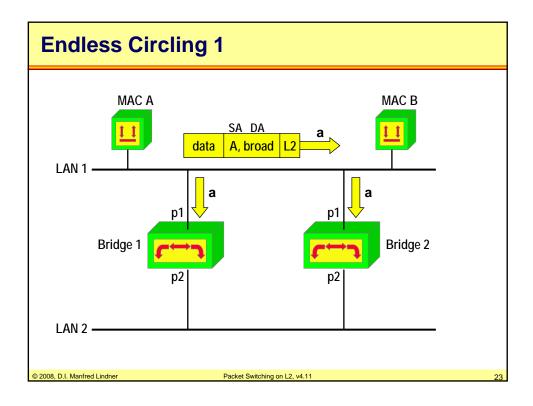

04

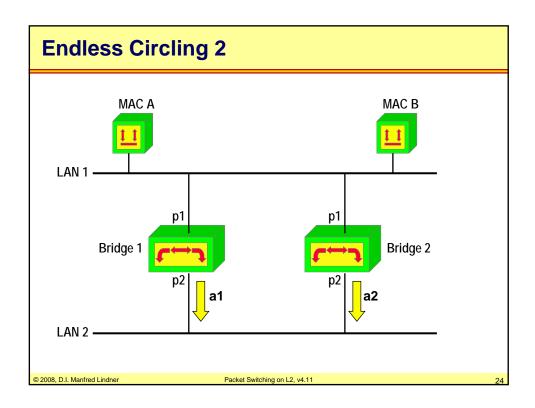

# **Parallel Paths**

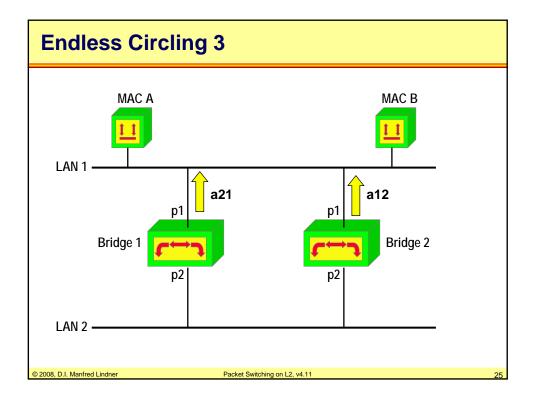

- parallel paths between two LAN segments cause
  - endless circling of frames with unknown destination
  - endless circling of broadcast-frames
  - endless circling of direct addressed frames during flooding phase
  - blocking of buffer-resources
- parallel paths in a more complex topology cause
  - overflow of all buffer-resources and stagnation of the LANs
  - Broadcast Storm
- to avoid these effects
  - Spanning Tree Protocol (STP)

acket Switching on L2, v4.11

# **Spanning Tree (IEEE 802.1D)**

# Spanning Tree Protocol (STP):

- takes care that there is always exact only one active path between any 2 stations
- implemented by a special communication protocol between the bridges
  - using BPDU (Bridge Protocol Data Unit) packets with MACmulticast address
- failure of active path causes activation of a redundant path

# main disadvantage of STP

 redundant lines or redundant network components cannot be used for load balancing

© 2008, D.I. Manfred Lindner

Packet Switching on L2, v4.1

0.5

# **Parameters for STP**

1

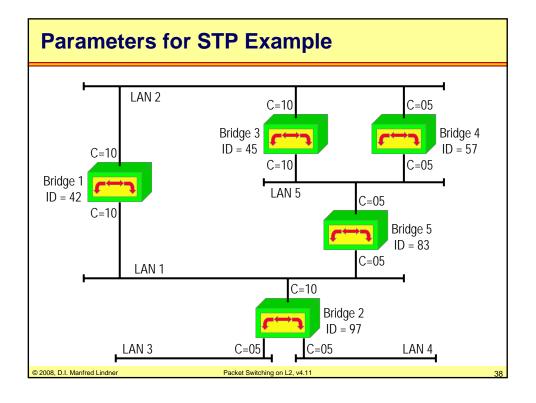

# Bridge Identifier (Bridge ID)

- combination of MAC-address and a priority number
  - typically, the lowest MAC-address of all ports is used for that
  - note: although bridge will not be seen by end systems, for bridge communication and management purposes a bridge will listen to one or more dedicated MAC addresses
  - Bridge-ID = priority# (2 Byte) + mac# (6 Byte)
- priority number can be configured by the administrator
  - default value is 32768
- lowest Bridge ID has highest priority
  - lowest configured priority number
- if you keep default values
  - the bridge with the lowest MAC address will have the highest priority

© 2008, D.I. Manfred Lindner

Packet Switching on L2, v4.1

# **Parameters for STP** 2 Port Cost (C) costs in order to access local interface - inverse proportional to the transmission rate – default cost = 1000 / transmission rate in Mbit/s so 10 Mbit/s Ethernet has a default Path Cost of 100 with occurrence of 1Gbit/s Ethernet rule was adapted - 100 Mbit/s = 19, 1Gbit/s = 4, 10Gbit/s = 2 can be configured to a different value by the administrator Port Identifier (Port ID) combination of port number and a priority number Port-ID = port priority#.port# configured by the administrator default port priority = 128

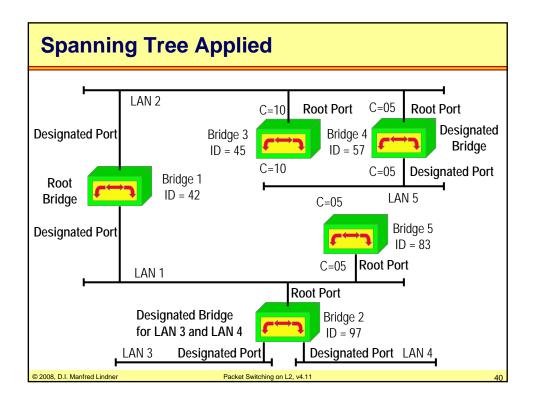

# **Spanning Tree Algorithm Summary**

- select the root bridge
  - · bridge with the lowest Bridge Identifier
- select the <u>root ports</u>
  - by computation of the shortest path from any other bridge to the root bridge
  - root port points to the shortest path towards the root
- select <u>one designated bridge</u> for every LAN segment which can be reached by more than one bridge
  - bridge with lowest root path costs on the root port side
  - corresponding port on other side is called designated port
- set the designated and root ports in <u>forwarding state</u>
- set all other ports in blocking state
- creates single paths from the root to all leaves (LAN segments) of the network

Packet Switching on L2, v4.1

# Format of STP Messages - BPDU Format

Prot. ID		BPDU Type		Root ID	Root Path Costs	Bridge ID	Port ID	Mess. Age		Hello Time	
2 Byte	1 Byte	1 Byte	1 Byte	8 Byte	4 Byte	8 Byte	2 Byte	2 Byte	2 Byte	2 Byte	2 Byte

BPDU ...... Bridge Protocol Data Unit (OSI term for this kind of message)

Root ID ...... Who seems to be or who is the root bridge (R-ID)?

Root Path Cost ....... How far is the root bridge away from me (RPC)?

Bridge ID ...... ID of bridge transmitting this BPDU (O-ID)

Port ID ..... port over which this BPDU was transmitted (P-ID)

© 2008, D.I. Manfred Lindner

acket Switching on L2, v4.1

41

# **BPDU Fields**

1

- Protocol Identifier:
  - 0000 (hex) for STP 802.1D
- Protocol Version:
  - 00 (hex) for version 802.1D (1998)
  - 02 (hex) for version 802.1D (2004)
- BPDU Type:
  - 00 (hex) for Configuration BPDU
  - 80 (hex) for Topology Change Notification (TCN) BPDU
- Root Identifier:
  - 2 bytes for priority (default 32768)
  - 6 bytes for MAC-address
- Root Path Costs in binary representation:
  - range 1-65535
- Bridge Identifier:
  - structure like Root Identifier

© 2008, D.I. Manfred Lindner

Packet Switching on L2, v4.11

<b>BPDU Fields</b>	2
--------------------	---

- Port Identifier:
  - 1 byte priority (default 128)
  - 1 byte port number
- Message Age (range 1-10s):
  - age of Configuration BPDU
  - transmitted by root-bridge initially using zero value, each passing-on (by designated bridge) increases this number
- Max Age (range 6-40s):
  - aging limit for information obtained from Configuration BPDU
  - basic parameter for detecting idle failures (e.g. root bridge = dead)
  - default 20 seconds
- Hello Time (range 1-10s):
  - time interval for generation of periodic Configuration BPDUs by root bridge
  - default 2 seconds

© 2008, D.I. Manfred Lindner

Packet Switching on L2, v4.1

40

# **BPDU Fields**

3

- Forward Delay (range 4-30s):
  - time delay for putting a port in the forwarding state
  - default 15 seconds
  - but that means 15 seconds listening plus 15 seconds learning
- Hello Time, Max Age, Forward Delay are specified by Root-Bridge
- Flags (a "1" indicates the function):
  - bit 8 ... Topology Change Acknowledgement (TCA)
  - bit 1 ... Topology Change (TC)
  - used in TCN BPDU's for signalling topology changes
    - TCN ... Topology Change Notification
    - in case of a topology change the MAC addresses should change quickly to another
      port of the corresponding bridging table (convergence) in order to avoid forwarding
      of frames to the wrong port/direction and not waiting for the natural timeout of the
      dynamic entry
    - the bridge recognizing the topology change sends a TCN BPDU on the root port as long as a CONF BPDU with TCA is received on its root port
    - bridge one hop closer to the root passes TCN BPDU on towards the root bridge and acknowledges locally to the initiating bridge by usage of CONF BPDU with TCA
    - when the root bridge is reached a flushing of all bridging table is triggered by the root bridge by usage of CONF BPDUs with TC and TCA set
    - the new location (port) is dynamically relearned by the actual user traffic

Packet Switching on L2, v4.11

# MAC Addresses / LLC / Network Diameter

- bridges use for STP-communication:
  - multicast address:

0180 C200 0000 hex

0180 C200 0001 to 0180 C200 000F are reserved

0180 C200 0010 hex All LAN Bridges Management Group Address

the DSAP/SSAP of LLC header

42 hex Bridge Spanning Tree Protocol

- Maximum Bridge Diameter
  - maximum number of bridges between any two end systems is 7 using default values for hello time, forward delay and max age
- For details of STP operation look to corresponding chapter in "Collection of all lectures of Manfred Lindner"

© 2008, D.I. Manfred Lindner

Packet Switching on L2, v4.1

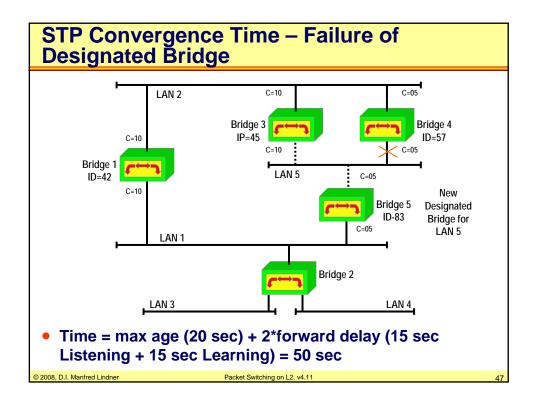

15

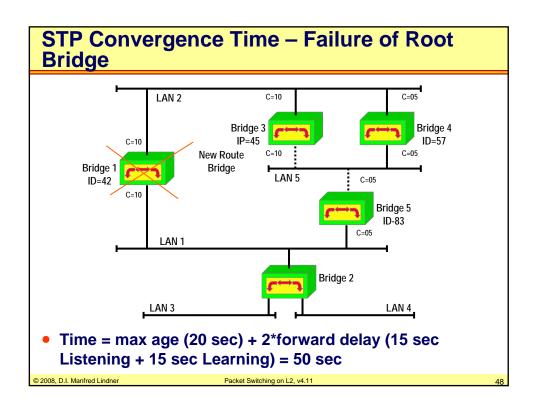

# **STP Error Detection**

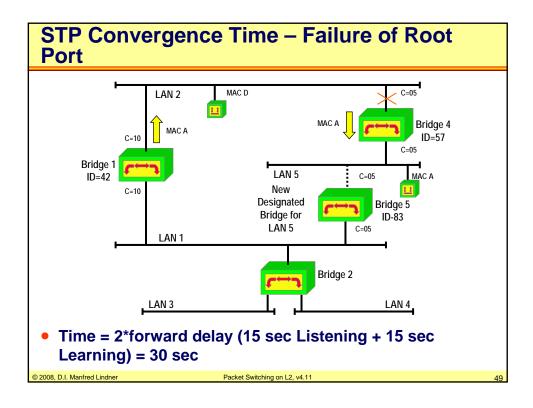

- normally the root bridge generates (triggers)
  - every 1-10 seconds (hello time interval) a Configuration BPDU to be received on the root port of every other bridge and carried on through the designated ports
  - bridges which are not designated are still listening to such messages on blocked ports
- if triggering ages out two scenarios are possible
  - root bridge failure
    - a new root bridge will be selected based on the lowest Bridge-ID and the whole spanning tree may be modified
  - designated bridge failure
    - if there is an other bridge which can support a LAN segment this bridge will become the new designated bridge

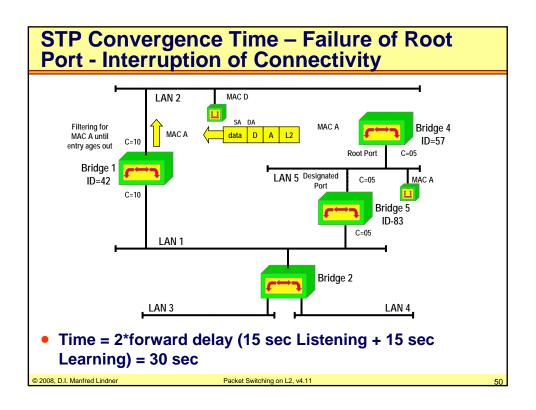

© 2008, D.I. Manfred Lindner

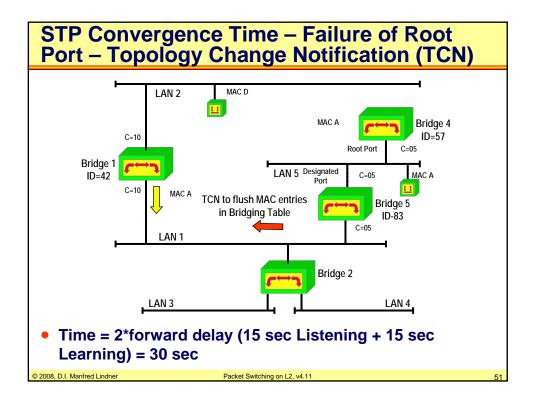

Packet Switching on L2, v4.11

# **Some STP Facts**

### disadvantages of STP

- active paths are always calculated from the root, but the actual information flow of the network may use other paths
  - note: network-manager can control this via Bridge Priority, Path Costs und Port Priority to achieve a certain policy under normal operation
  - hence STP should be designed to overcome plug and play behaviour of default values
- redundant paths cannot be used for load balancing
  - redundant bridges may be never used if there is no failure of the currently active components
  - for remote bridging via WAN the same is true for redundant WAN links
- convergence time between 30 and 50 seconds
  - note: in order to improve convergence time Rapid Spanning Tree Protocol has been developed (802.1D version 2004)

© 2008, D.I. Manfred Lindner

Packet Switching on L2, v4.11

# **Agenda**

- Introduction
- Transparent Bridging Basics
- Spanning Tree Protocol
- Rapid Spanning Tree Protocol
- Comparison L3 Routing versus L2 Bridging

© 2008, D.I. Manfred Lindner

Packet Switching on L2, v4.1

---

# Introduction

- Rapid Spanning Tree (RSTP)
  - IEEE 802.1D version 2004 (former IEEE 802.1w)
  - Can be seen as an evolution of the Spanning Tree Protocol (STP; IEEE 802.1D)
  - Capable of reverting back to 802.1D version 1998
  - Convergence time reduced to few seconds !!!

# Terminology slightly changed

- Blocking port role is split into the Backup and Alternate port roles
  - Alternate port
  - Backup port
- Root port and Designated port roles still remain the same
- New port state
  - Discarding (see next slides for details)

© 2008, D.I. Manfred Lindner

Packet Switching on L2, v4.11

5/

# **Port States Comparison**

STP (802.1d) Port State	RSTP (802.1w) Port State	Is Port included in active Topology?	Is Port learning MAC addresses?	
disabled	discarding	No	No	
blocking	discarding	No	No	
listening	discarding	Yes	No	
learning	learning	Yes	Yes	
forwarding	forwarding	Yes	Yes	

© 2008, D.I. Manfred Lindner

acket Switching on L2, v4.1

--

# **Port Roles**

### Root Port Role

 Receives the best BPDU (so it is closest to the root bridge)

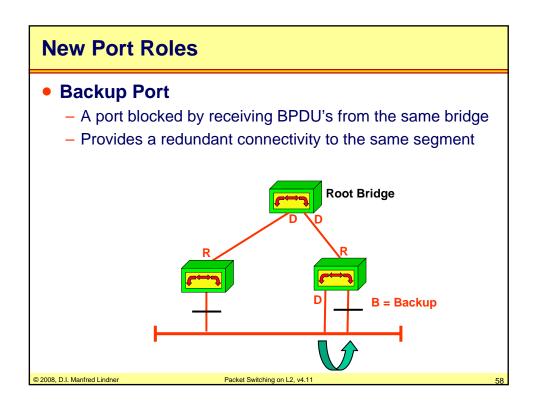

# Designated Port Role

- A port is designated if it can send the best BDPU on the segment to which it is connected
- On a given segment, there can be only one path toward the root-bridge

© 2008, D.I. Manfred Lindner

Packet Switching on L2, v4.11

### **BPDU Flag Field – New Values** Few changes have been introduced by RSTP - TC and TCA used by old STP RSTP also uses the 6 remaining bits 2 3 5 0 1 6 4 **Topology Change ACK (TCA)** Agreement Forwarding Learning 00 Unknown Port role 01 Alternate/Backup **Proposal** 10 Root **Topology Change (TC)** 11 Designated

# **NEW BPDU Handling**

# Faster Failure Detection

- BPDU's acting now as keepalives messages
  - Different to the 802.1D STP a bridge now sends a BPDU with its current information every <hello-time> seconds (2 by default), even if it does not receive any from the root bridge
- If hellos are not received for 3 consecutive times, port information is invalidated
  - because BPDU's are now used as keep-alive mechanism between bridges
- If a bridge fails to receive BPDU's from a neighbor, the connection has been lost
- No more max age and message age fields
  - · Hop count is used instead

© 2008, D.I. Manfred Lindner

Packet Switching on L2, v4.1

# **Proposal / Agreement**

- Explicit handshake between bridges
  - Upon link up event the bridge sends a proposal to become designated for that segment
  - Remote bridge responses with an agreement if the port on which it received the proposal is the root port of the remote bridge
  - As soon as receiving an agreement, bridge moves the port to the forwarding state

© 2008, D.I. Manfred Lindner

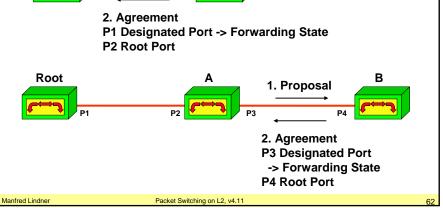

Packet Switching on L2, v4.1

61

# **Proposal/Agreement Sequence**

1. Proposal

 Suppose a new link is created between the root and switch A and then a new switch B is inserted

# **Rapid Transition to Forwarding State**

- Most important feature in 802.1w
- The legacy STP was passively waiting for the network to converge before turning a port into the forwarding state
- New RSTP is able to actively confirm that a port can safely transition to forwarding
- Real feedback mechanism, that takes place between RSTP-compliant bridges
- To achieve fast convergence on a port, the protocol relies upon 2 new variables
  - Edge ports
  - Link type

© 2008, D.I. Manfred Lindner

Packet Switching on L2, v4.11

00

# **Rapid Transition to Forwarding State**

# Edge Ports

 Ports, which are directly connected to end stations cannot create bridging loops in the network and can thus directly perform on link setup transition to forwarding, skipping the listening and learning states

# Link type

- Is automatically derived from the duplex mode of a port
  - A port operating in full-duplex will be assumed to be point-to-point
  - A port operating in half-duplex will be assumed to be a shared port

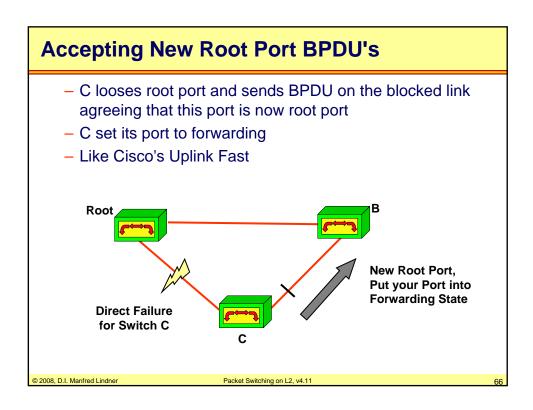

# RSTP can only achieve rapid transition to forwarding

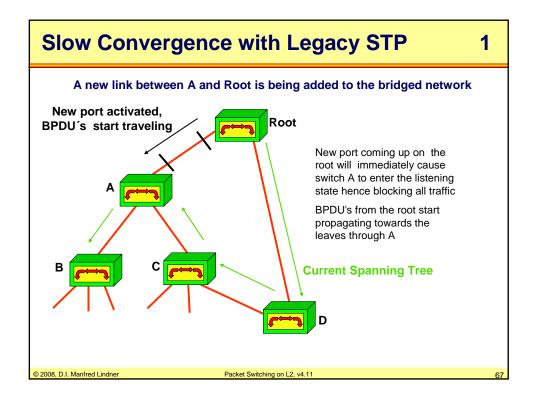

- On edge ports
- On point-to-point links (trunks between L2 switches)
- But not on shared Ports

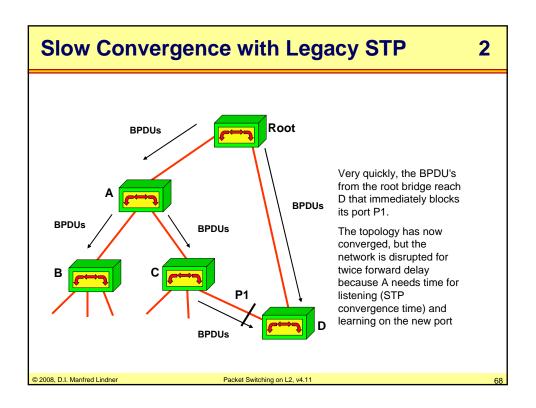

© 2008, D.I. Manfred Lindner

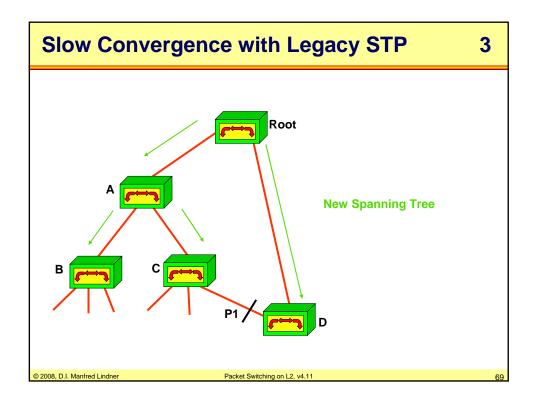

Packet Switching on L2, v4.11

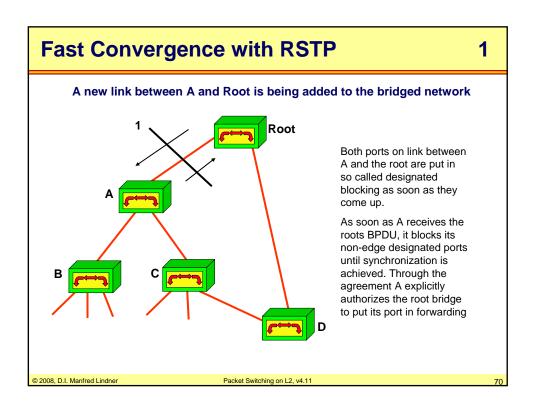

# Accepting Inferior BPDU's - B looses root port and sends BPDU claiming to be the root - C immediately becomes designated for the blocked link between C and B and sends a proposal to B - B sends an agreement and C set its port to forwarding - Like Cisco's Backbone Fast Indirect Failure for Switch C Root Inferior BPDU "I am the root"

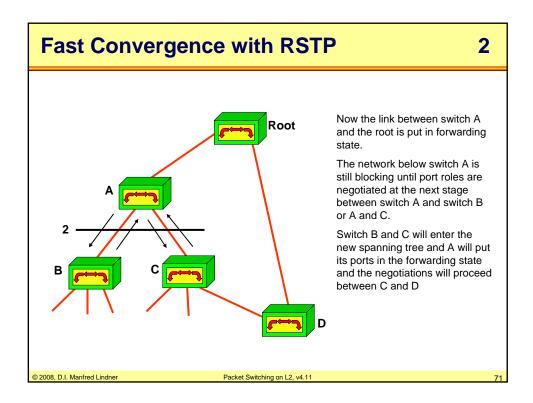

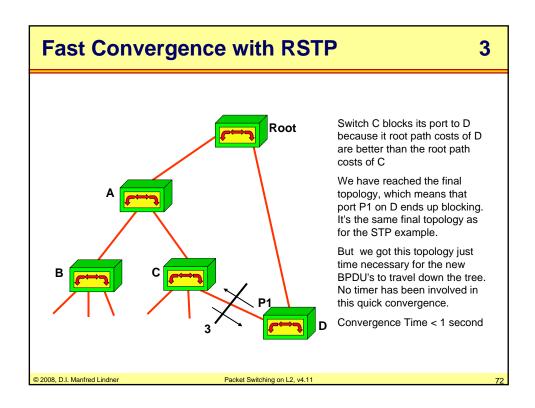

# **Topology Change Detection**

- When a RSTP bridge detects a topology change, the following happens:
  - It starts the TC While timer with a value twice the hello time for all its non-edge designated ports and its root port if necessary
  - It flushes the MAC addresses associated with all these ports from the MAC bridging table

© 2008, D.I. Manfred Lindner

Packet Switching on L2, v4.1

70

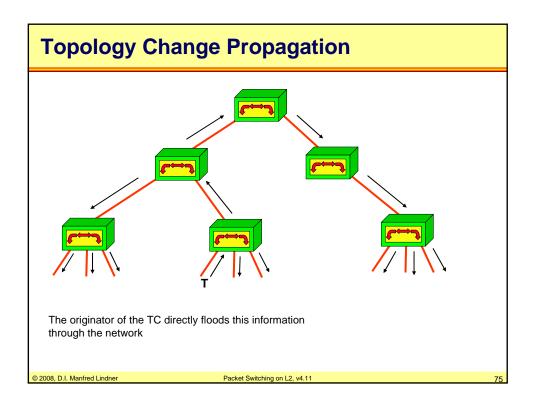

# **Topology Change Propagation**

- When a bridge receives a BPDU with the TC bit set from a neighbor, the following happens:
  - It clears the MAC addresses learnt on all its ports except the one that received the topology change
  - It starts the TC While timer and sends BPDU's with TC set on all its designated ports and root port (RSTP no longer uses the specific TCN BPDU, unless a legacy bridge need to be notified)

© 2008, D.I. Manfred Lindner

Packet Switching on L2, v4.1

7/

# **Agenda**

- Introduction
- Transparent Bridging Basics
- Spanning Tree Protocol
- Rapid Spanning Tree Protocol
- Comparison L3 Routing versus L2 Bridging

© 2008, D.I. Manfred Lindner

Packet Switching on L2, v4.11

### Router

## router forwards packets

based on <u>layer 3 addresses</u> and protocols

### layer 3 address

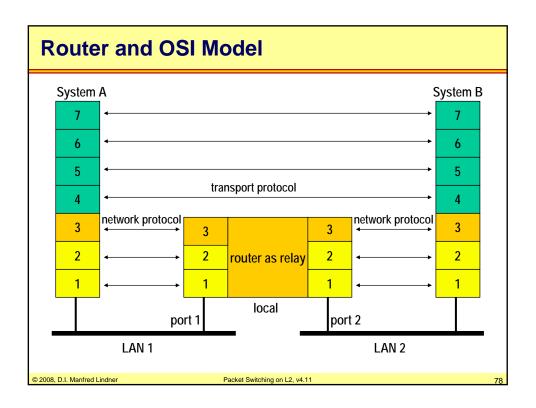

- structured versus unstructured layer 2 address
  - at least two level hierarchy: subnet and end system (host)
- hardware independent
- identifies a certain end system located in one subnet in a non-ambiguous way
- a structured address is laid upon the unstructured MACaddress

#### router connects

subnets knowing the best path to other subnets

© 2008, D.I. Manfred Lindner

Packet Switching on L2, v4.11

# **Requirements for Routers**

## consistent layer-3 functionality

- for entire transport system
- from one end-system over all routers in between to the other end-system
- hence routing is not protocol-transparent
  - all elements must speak the same "language"

### end-system

- must know about default router
- on location change, end-system must adjust its layer 3 address

## to keep the routing tables consistent

 routers must exchange information about the network topology by using <u>routing-protocols</u>

© 2008, D.I. Manfred Lindner

Packet Switching on L2, v4.1

70

# **Routing Facts**

1

## • in contrast to bridges

- router maintains only the subnet-part of the layer 3 addresses in its routing table
- the routing table size is direct <u>proportional to the number</u> of <u>subnets</u> and not to the number of end-systems

## transport on a given subnet

still relies on layer 2 addresses

# end systems forward data packets for remote destinations

- to a selected router using the router's MAC-address as destination
- only these packets must be processed by the router

© 2008, D.I. Manfred Lindner

Packet Switching on L2, v4.11

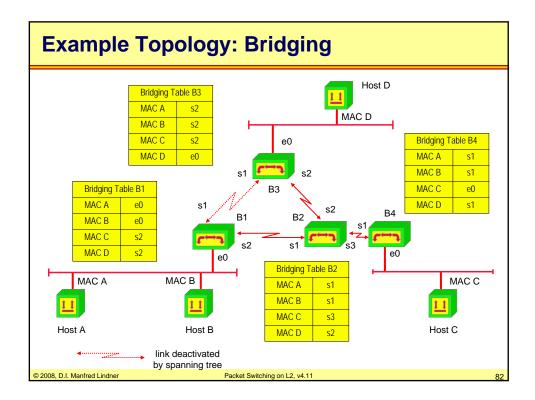

## **Routing Facts**

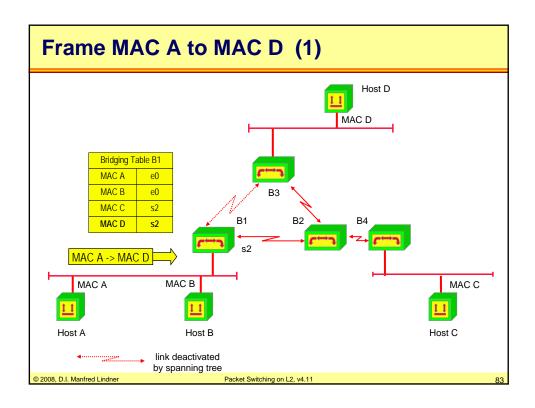

2

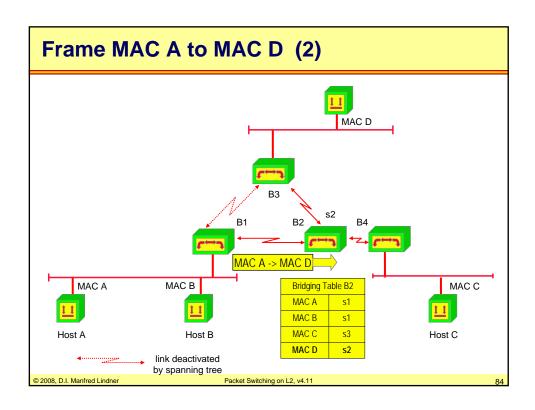

- flow control between router and end system is principally possible
  - end systems knows about the local router
- broadcast/multicast-packets in the particular subnet
  - are blocked by the router so broad/multicast traffic on the subnets doesn't stress WAN connections
- independent of layer 1, 2
  - so coupling of heterogeneous networks is possible
- routers can use redundant paths
  - meshed topologies are usual
- routers can use parallel paths for load balancing

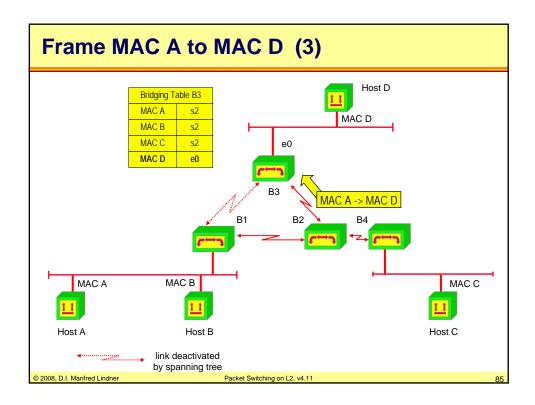

© 2008, D.I. Manfred Lindner

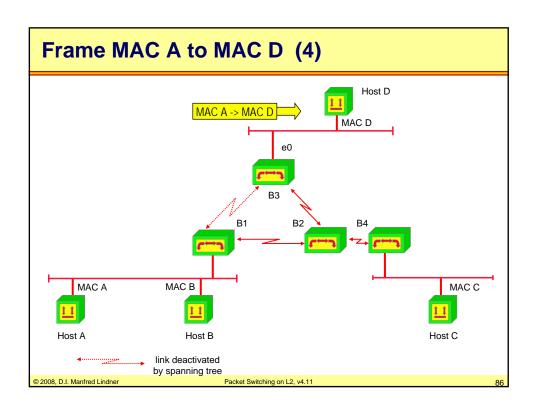

Packet Switching on L2, v4.1

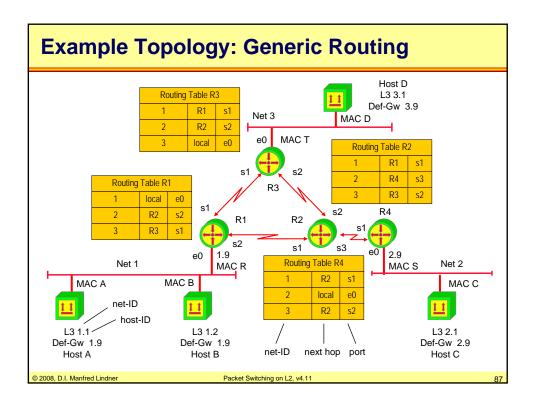

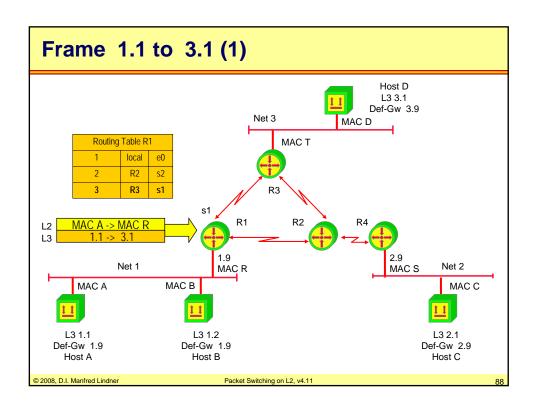

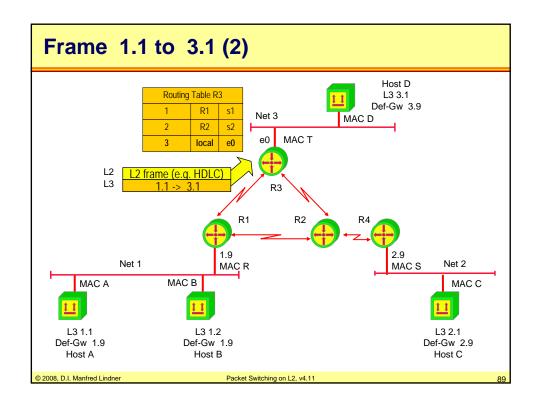

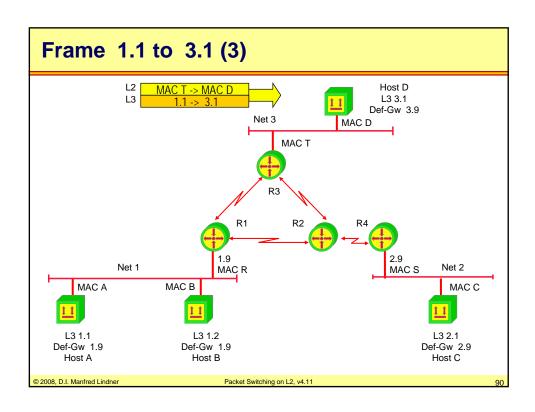

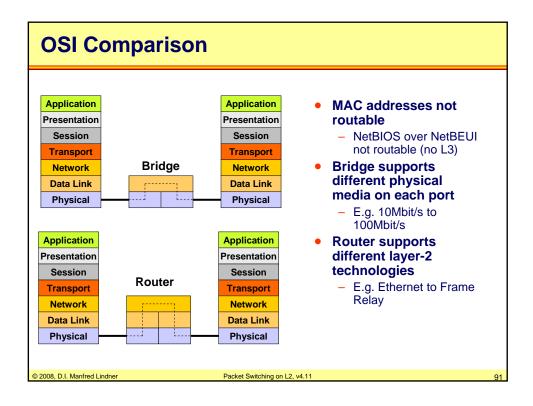

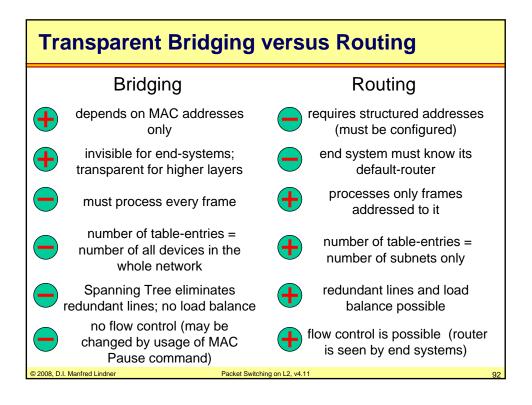

# Transparent Bridging versus Routing

## **Bridging**

# no LAN/WAN coupling because of high traffic (broadcast domain!)

faster, because implemented in HW; no address resolution

location change of an endsystem does not require updating any addresses

## Routing

router knows best way for each frame

slower, because usually implemented in SW; address resolution (ARP) necessary

location change of an endsystem requires adjustment of layer 3 address (may be solved by DHCP)

© 2008, D.I. Manfred Lindner

Packet Switching on L2, v4.11

03

# **Transparent Bridging versus Routing**

#### **Bridging**

#### spanning tree necessary against endless circling of frames and broadcast storms

## Routing

- routing-protocols necessary to determine network topology
- but today's L2 switches can improve network performance by enabling full duplex, collisionfree subnets
- MAC address resolution of routers is considered as unnecessary overhead -> trend goes to layer 3 switching (fast routing)

© 2008, D.I. Manfred Lindner

Packet Switching on L2, v4.1

## **Most Important!**

- bridge separates LAN into
  - multiple collision domains
- but a <u>bridged</u> network is still
  - one broadcast domain
  - broadcast frames are always flooded
- router separates the whole Inter-network
  - into multiple broadcast domains
  - broadcast frames arriving on a LAN are always stopped at the router
  - they can't leave their origin LAN

© 2008, D.I. Manfred Lindner

Packet Switching on L2, v4.1

0.5

## **Ethernet Switching**

- Ethernet switch is basically a bridge, differences are only:
  - faster because implemented in HW
  - multiple ports
  - improved functionality (e.g. VLAN)
  - note: packet switching / connectionless mode with frame forwarding based on unstructured MAC addresses
- don't confuse it with WAN Switching!
  - e.g. X.25 switch, Frame Relay switch, ATM switch
  - completely different!
  - that is packet switching / connection-oriented mode with forwarding based on local connection identifiers

© 2008, D.I. Manfred Lindner

Packet Switching on L2, v4.1
