

Address Resolution

ARP, RARP, Proxy ARP

- **Address Resolution Protocol (ARP)**
 - ◆ IP Routing Basics
 - ◆ IP Forwarding and ARP
- **RARP**
- **Proxy ARP**
- **ICMP**
 - ◆ IP Forwarding and ICMP

Address Resolution Protocol

Why ARP?

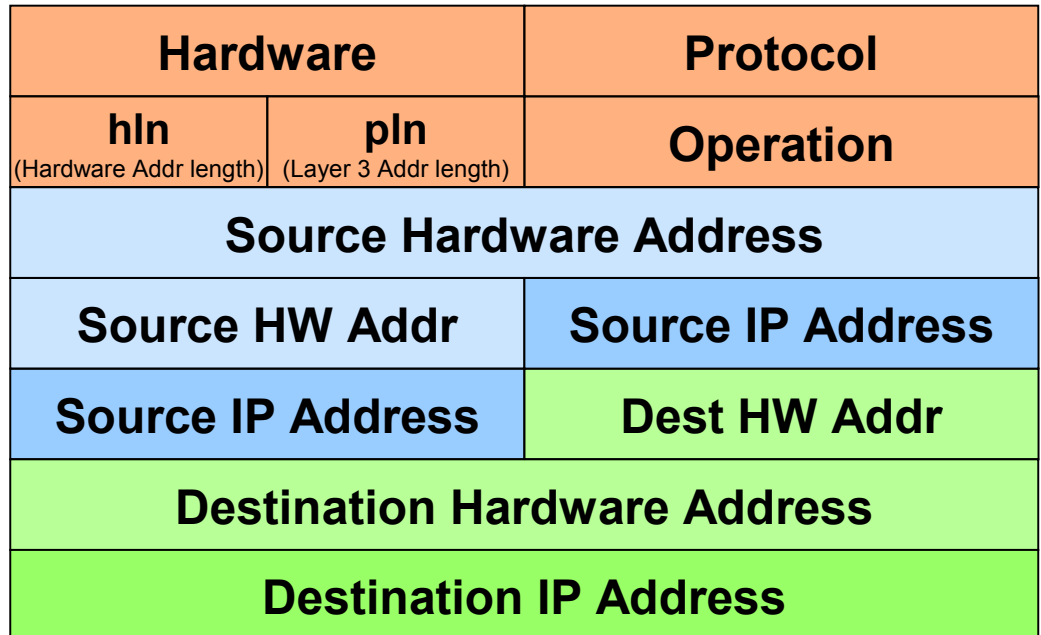

- **On a multipoint network every station needs a layer-2 address**
- **When IP packets should be sent to a local destination the sender must first determine the corresponding layer-2 address**
- **The layer-2 address could be a MAC address, a DLCI (Frame-Relay) or similar**
 - ◆ **In this chapter we only focus on Ethernet**

ARP Format

Ethernet II Frame

0 8 16 24 32

Example ARP Request (Ethernet / IP):

Hardware: 6 (IEEE802.x)

Protocol: 0x0800 (IP)

hln: 6 (MAC Address in Bytes)

pln: 4 (IP Address in Bytes)

Operation: 1 (ARP Request)

Source HW Addr: hex: 00 60 97 bc 88 f1

Source IP Addr: 192.168.1.1

Dest HW Addr: hex: ff ff ff ff ff ff

Dest IP Addr: 192.168.1.254

Routing Differences

- Routing = finding a path to a destination address
- **Direct delivery** performed by host
 - ◆ Destination network = local network
- **Indirect delivery** performed by router
 - ◆ Destination network \neq local network
 - ◆ Packet is forwarded to **default gateway**

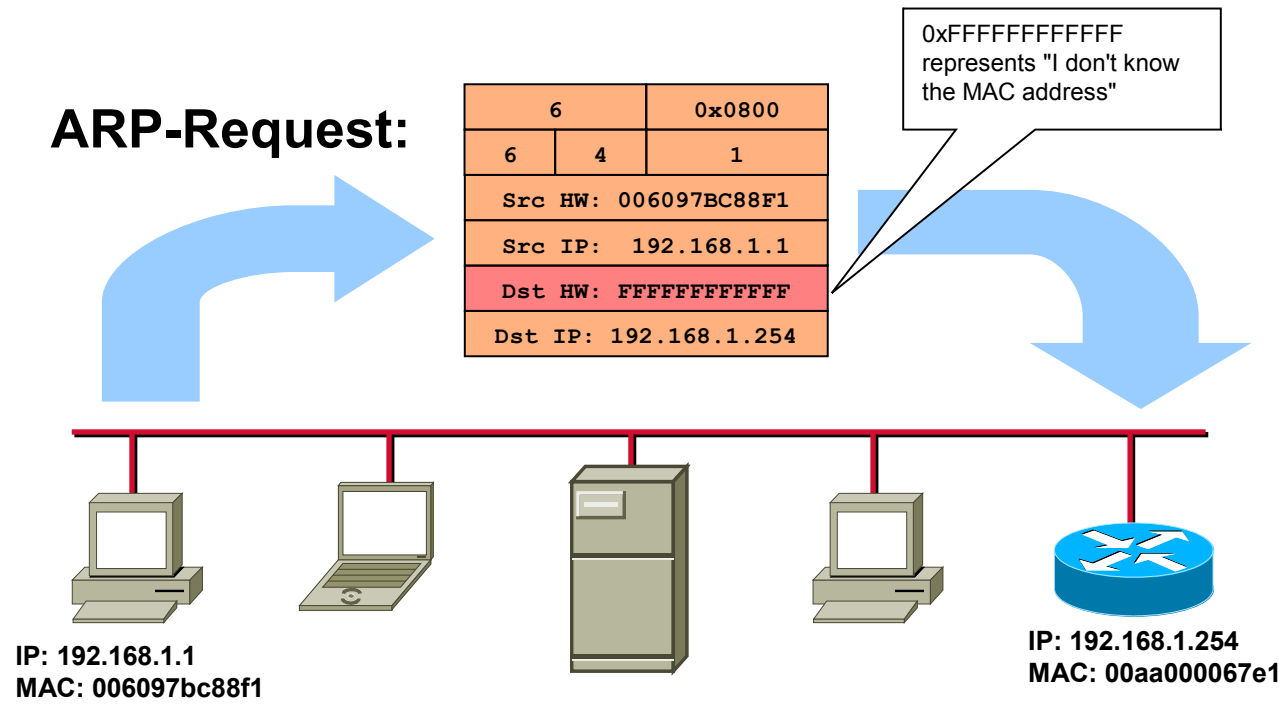

- **IP host checks if packet's destination network is identical with local network**
 - ◆ **By applying the configured subnet mask of the host's interface**
- **If destination network = local network then the L2 address of the destination is discovered using ARP**
 - ◆ **Remember: not necessary for point-to-point connections**

Direct Delivery

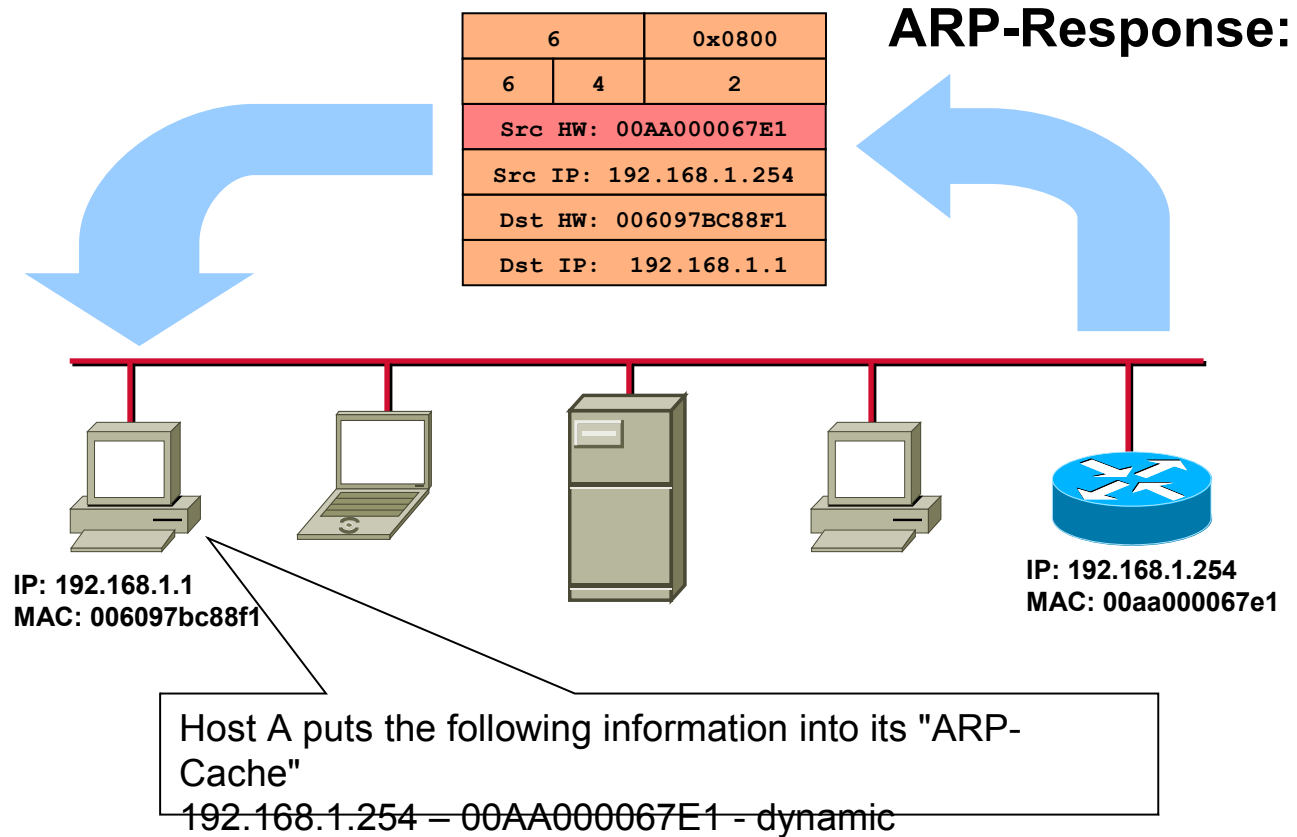

- Sent as Broadcast

Direct Delivery

- Response is unicast

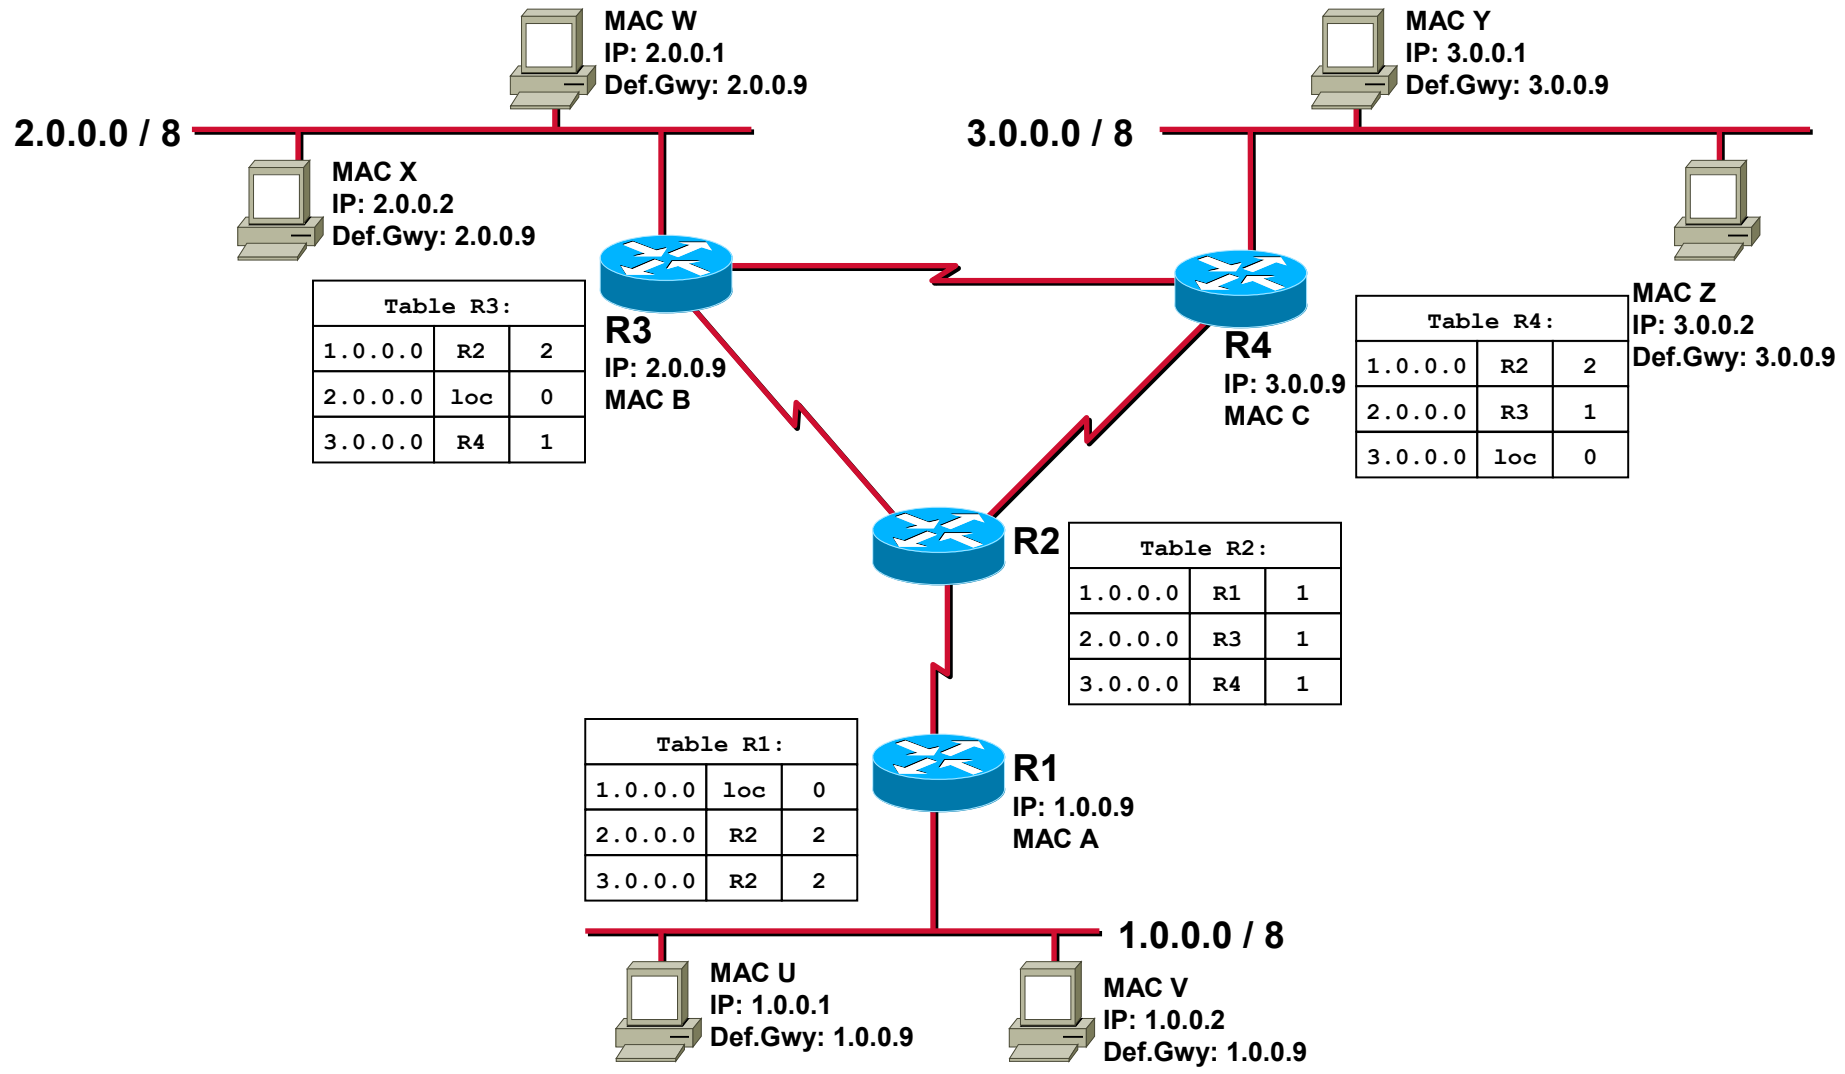

- Learned MAC addresses are stored in an **ARP-cache**
 - ◆ Aging timer: **20 minutes**
- IP hosts have also routing tables !
 - ◆ But typically only a static route to the default gateway is entered
 - ◆ Default gateway for indirect delivery

Using the Default Gateway

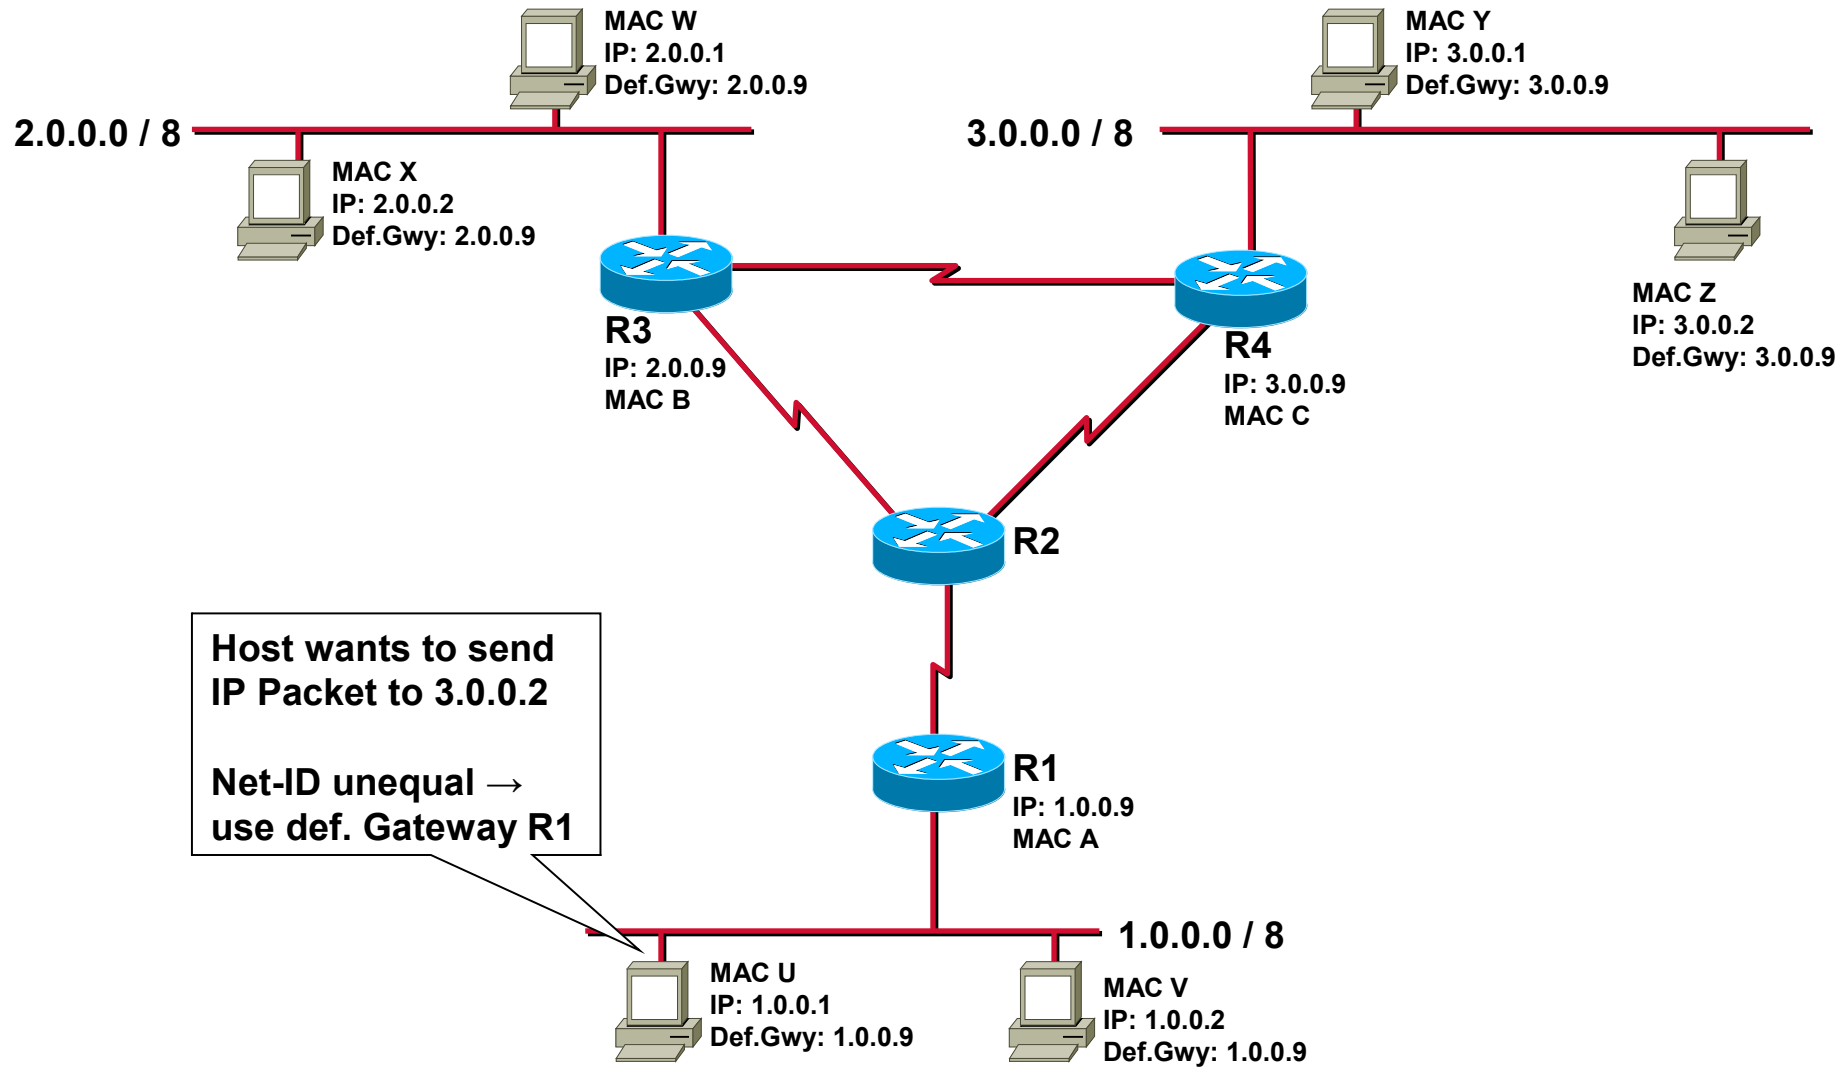

- **Default gateway delivers packet in behalf of its host using a routing table**
- **Host must determine MAC address of default gateway using ARP**
- **IP datagram is handed over to default gateway**

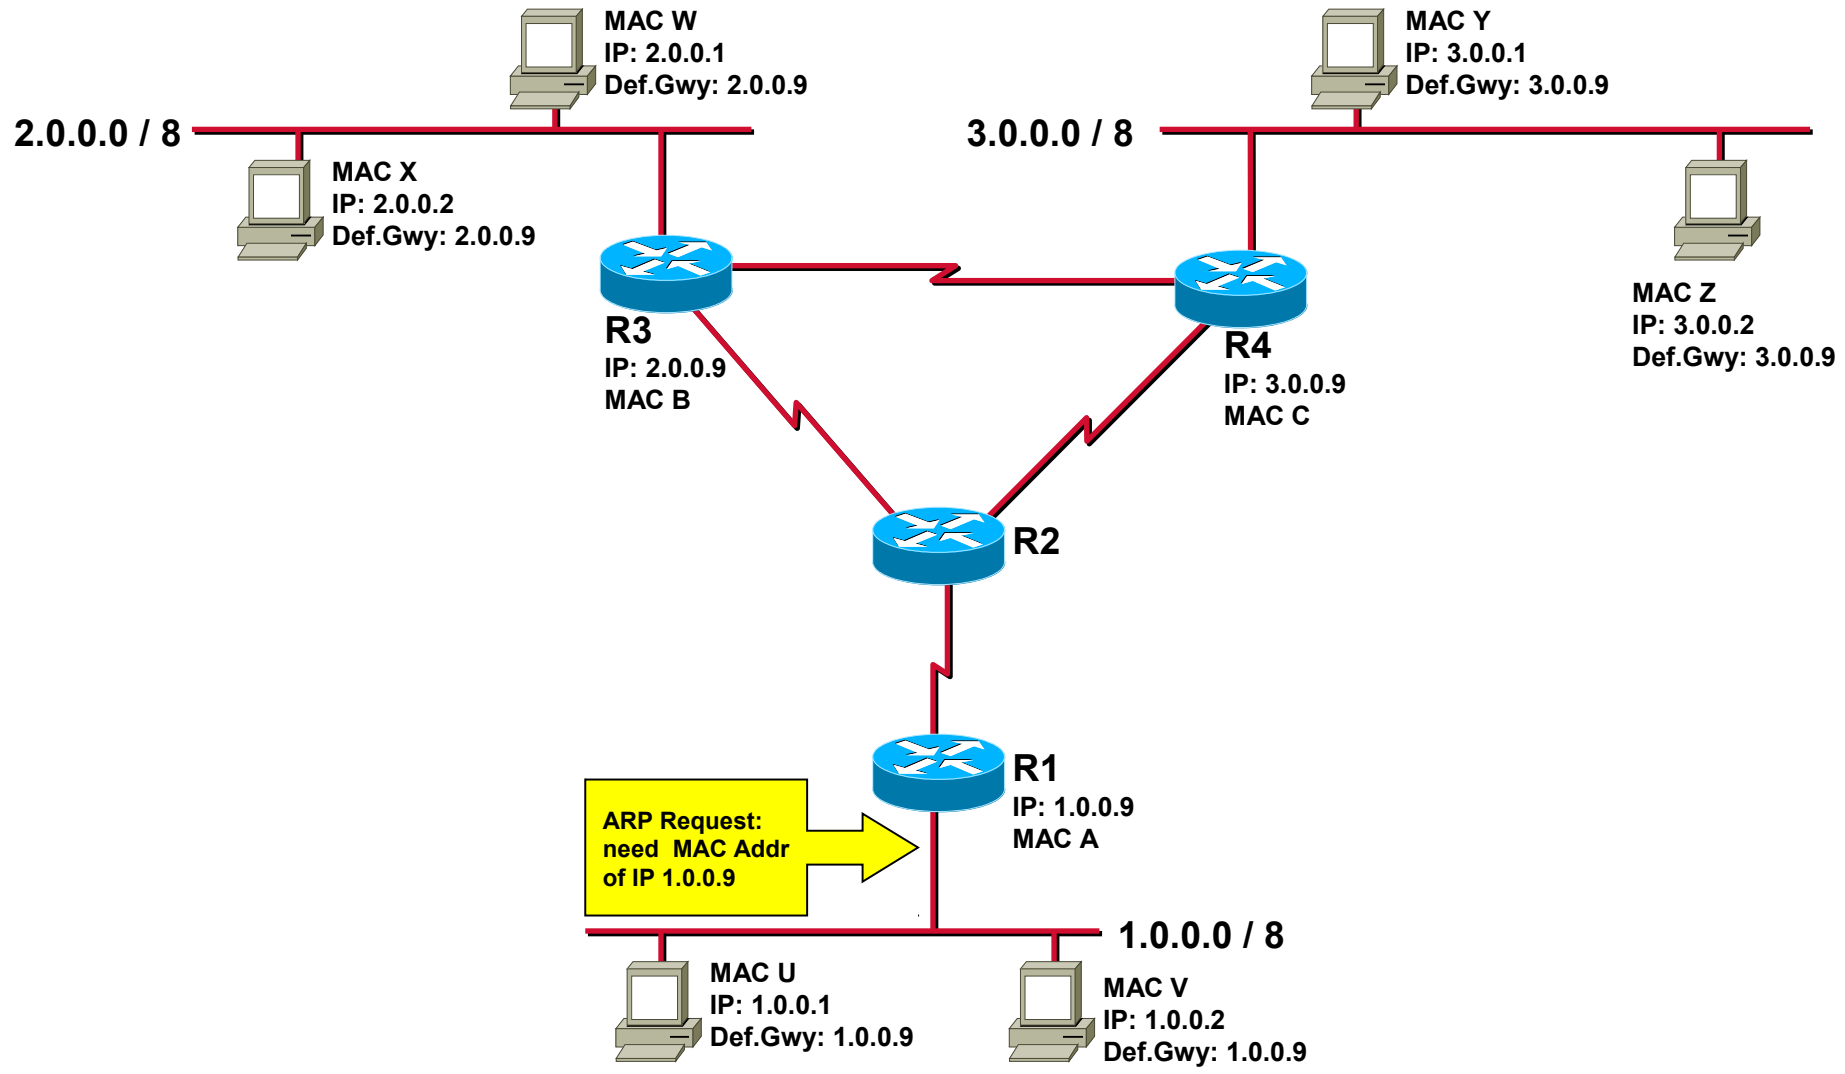

Indirect Delivery (1)

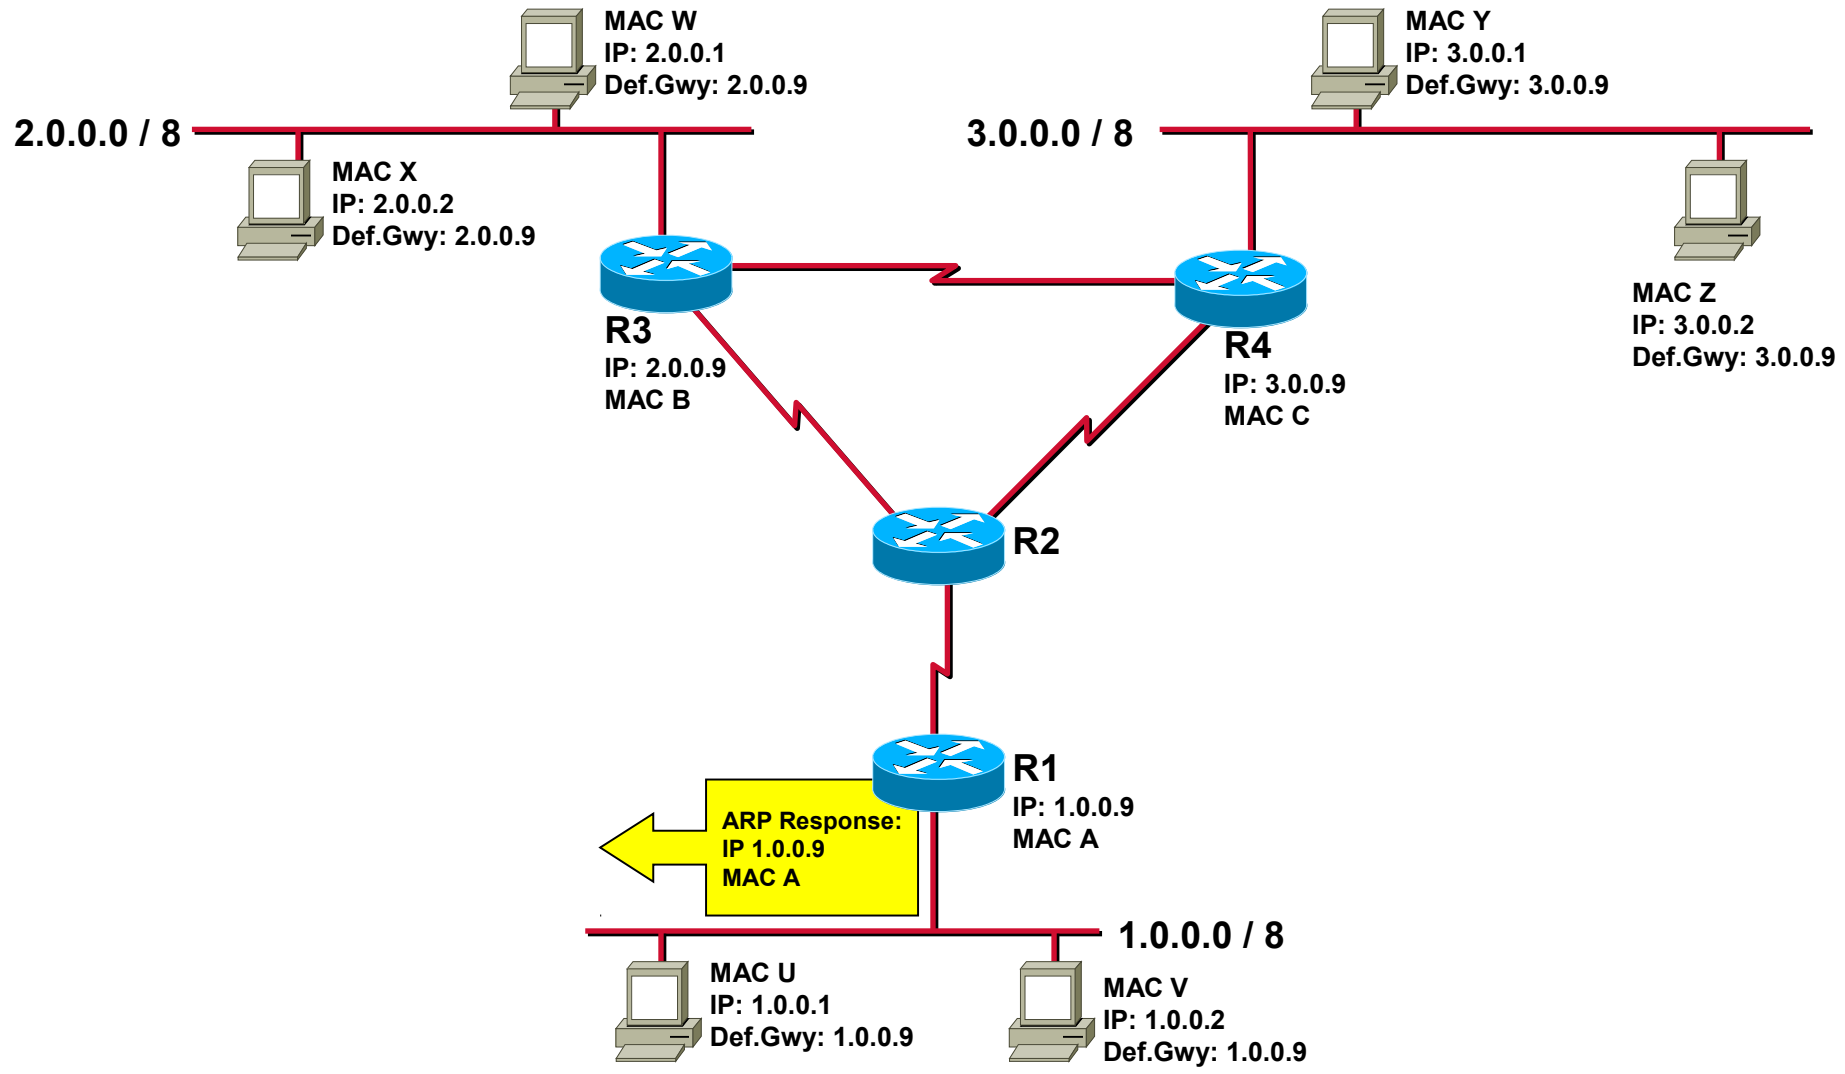

Indirect Delivery (2)

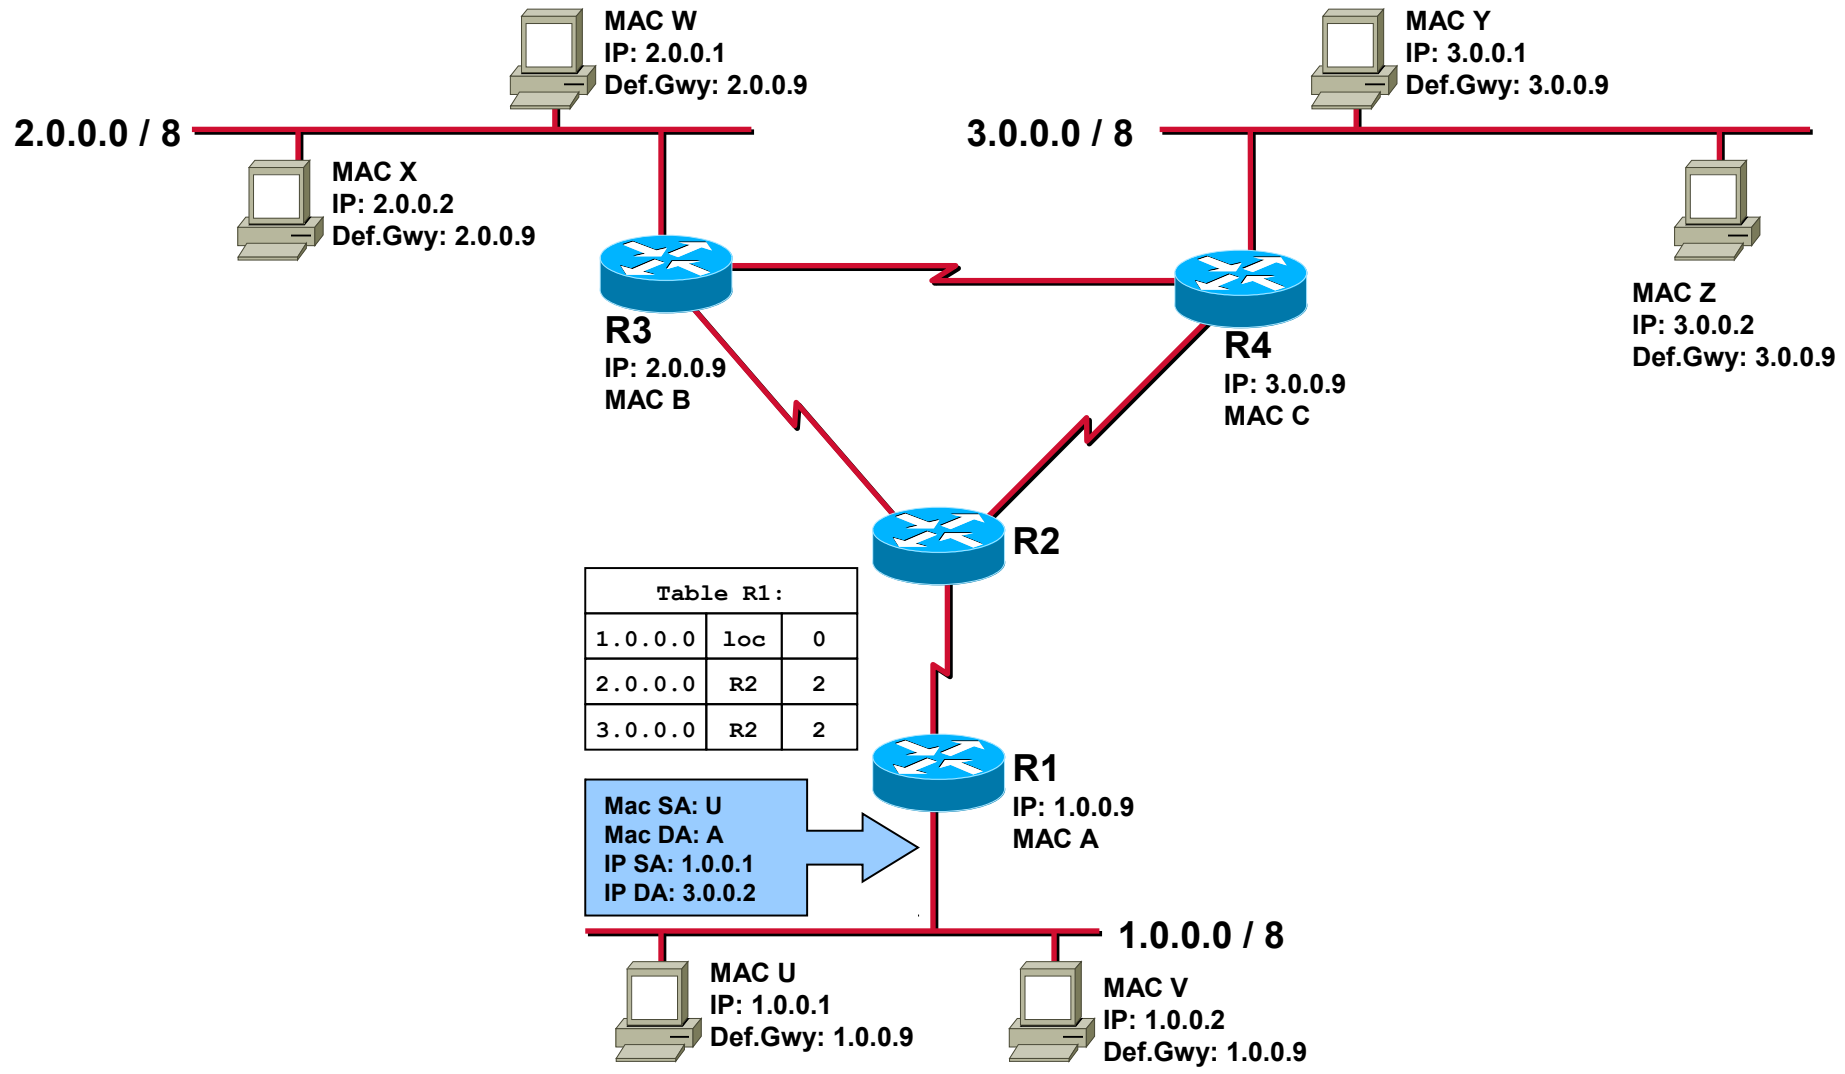

Indirect Delivery (3)

Reverse ARP

Reverse ARP (RARP)

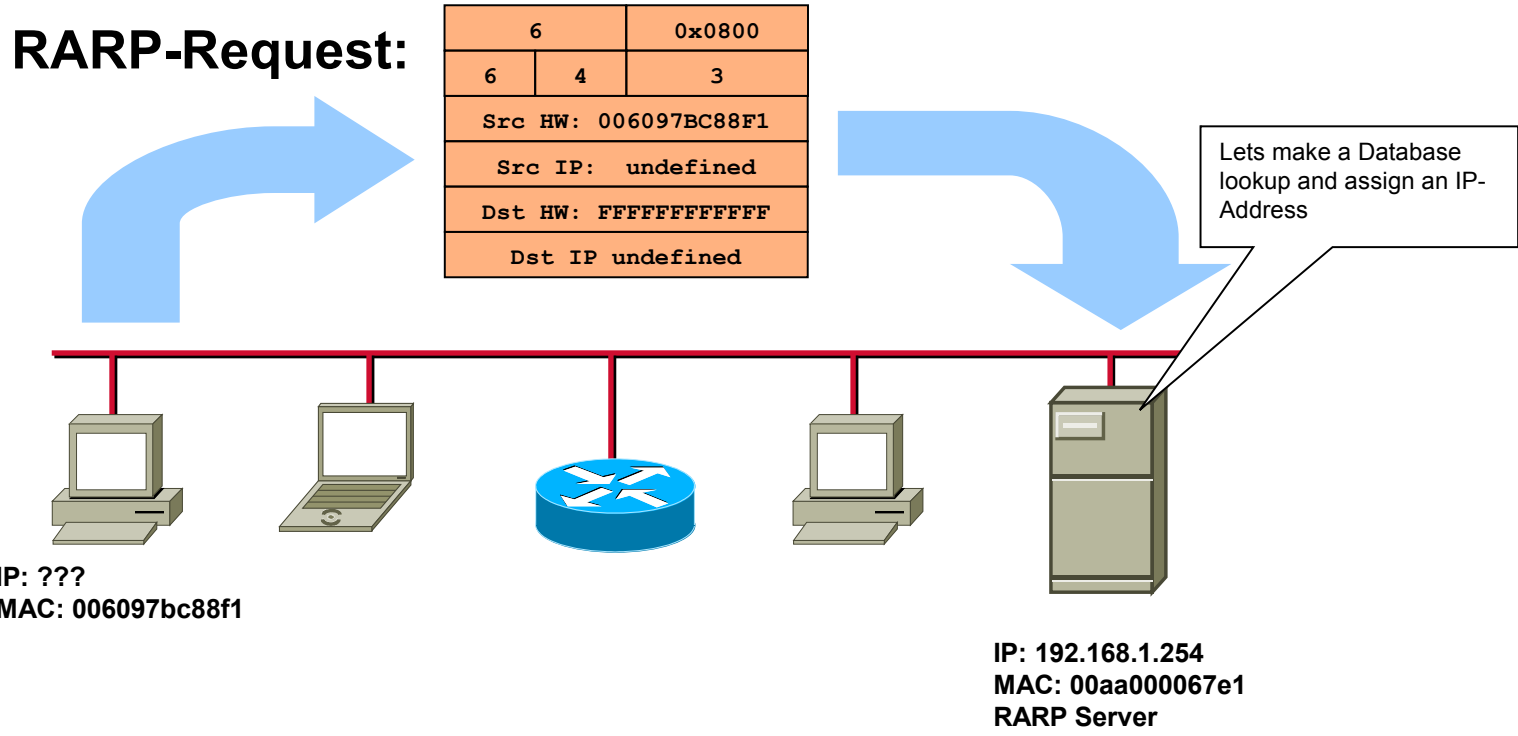

- **ARP assumes, that an IP station knows its IP address (stored in NVRAM, on hard disk, in config file etc.).**
- **Diskless Machines usually don't have such means so they must retrieve an IP address for network booting.**
- **RARP (Reverse ARP) provides IP addresses for unconfigured stations.**
- **RFC 903**

Reverse ARP (RARP)

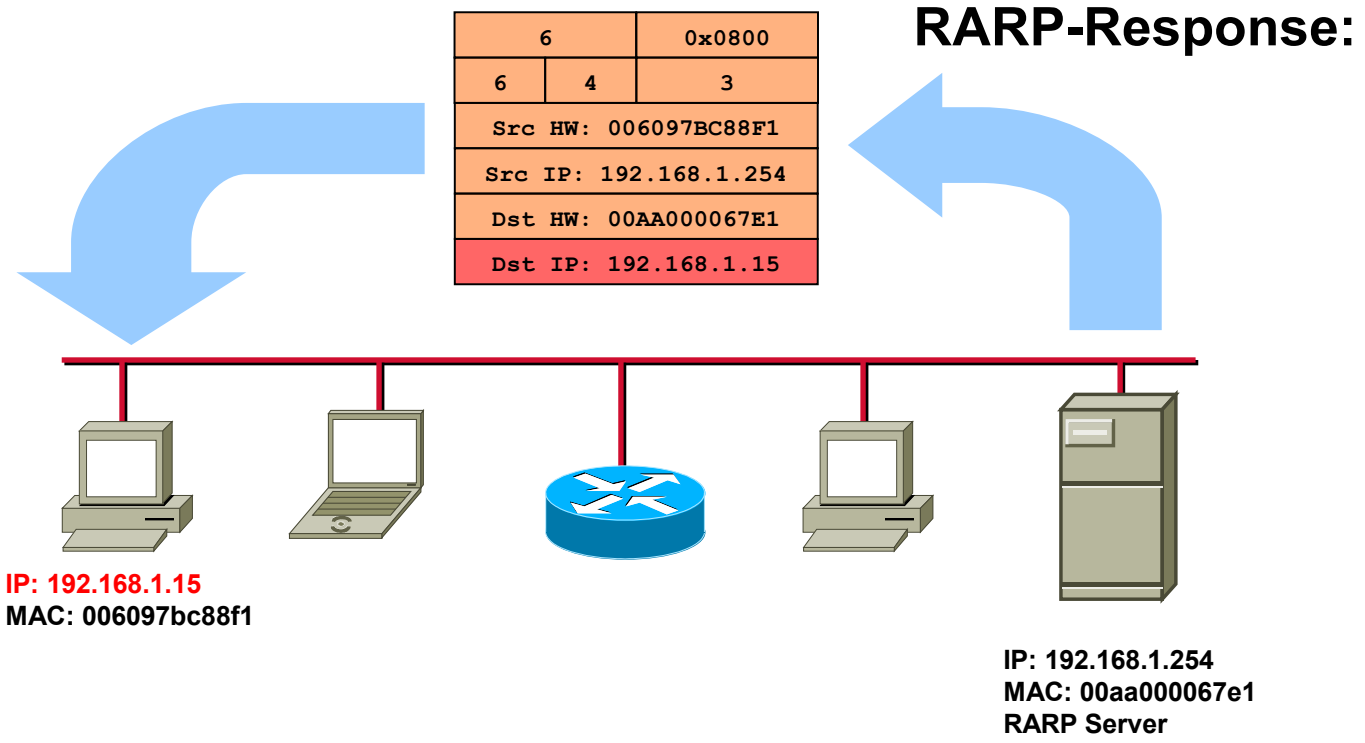

- A station sends a RARP request broadcast.
- One station, the RARP server, looks up the IP address for that MAC address in a database and replies.
- Newer methods:
 - ◆ BOOTP
 - ◆ DHCP

Reverse ARP (RARP)

Reverse ARP (RARP)

Proxy ARP

"The ARP Hack"

Proxy ARP (1)

- Router connect only networks with different net-IDs
- Router with Proxy ARP enabled also connect networks with **same Net-ID**
 - ◆ Router replies on ARP request in behalf of station in other segment
 - ◆ Security or performance reasons
- “proxy” simply means *“instead of”*

Proxy ARP (2)

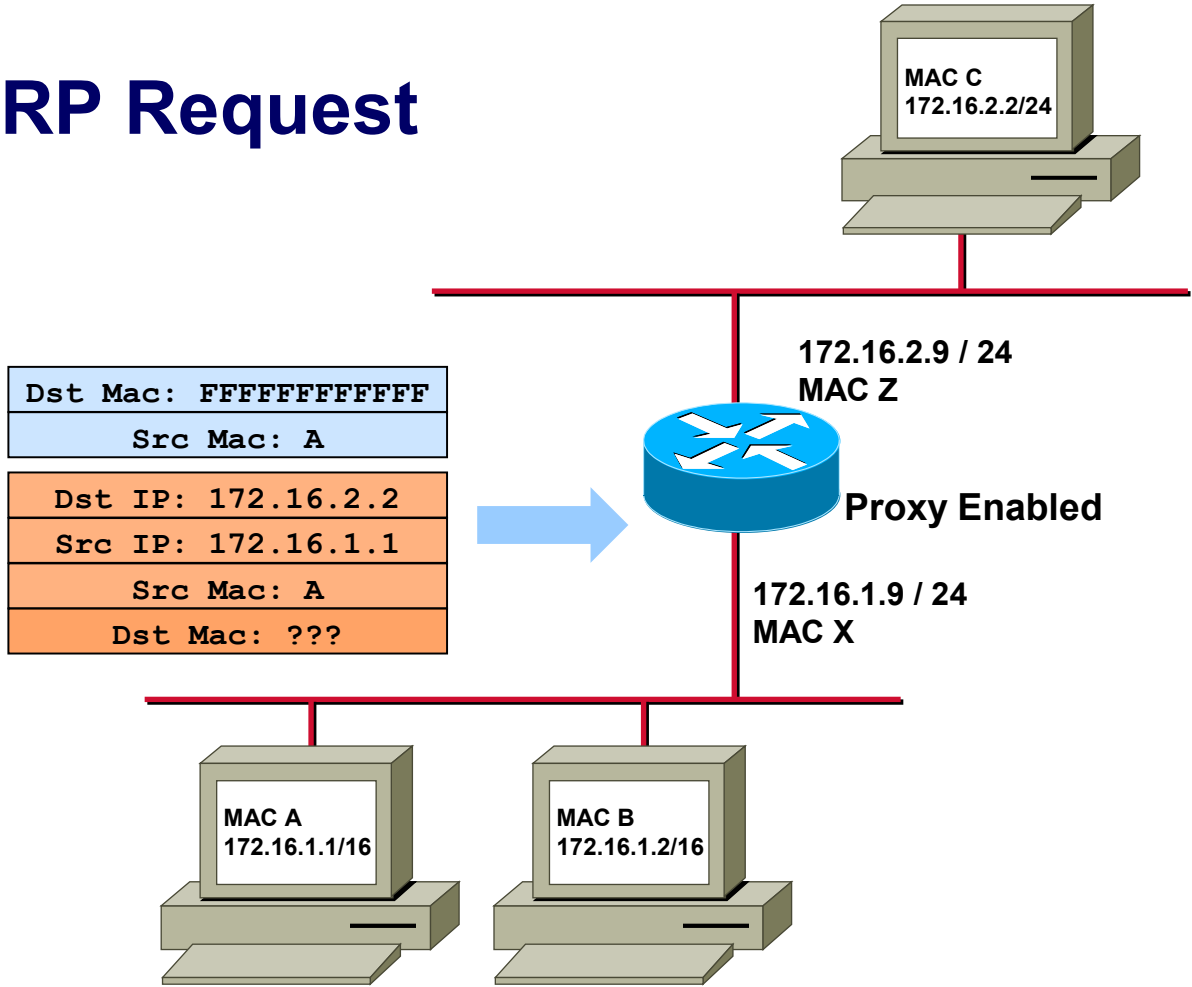

- **Using Proxy ARP on routers, hosts do not need default gateway or routing entries to reach other subnets**
- **Default router's address = own interface address**
 - ◆ **Force ARP for every destination address**
- **If the local router is configured for Proxy-ARP it replies with an ARP response claiming to be the destination host**
 - ◆ **Then accepts and forward the IP packet**
 - ◆ **Cisco routers have Proxy-ARP enabled by default**

Proxy ARP (3)

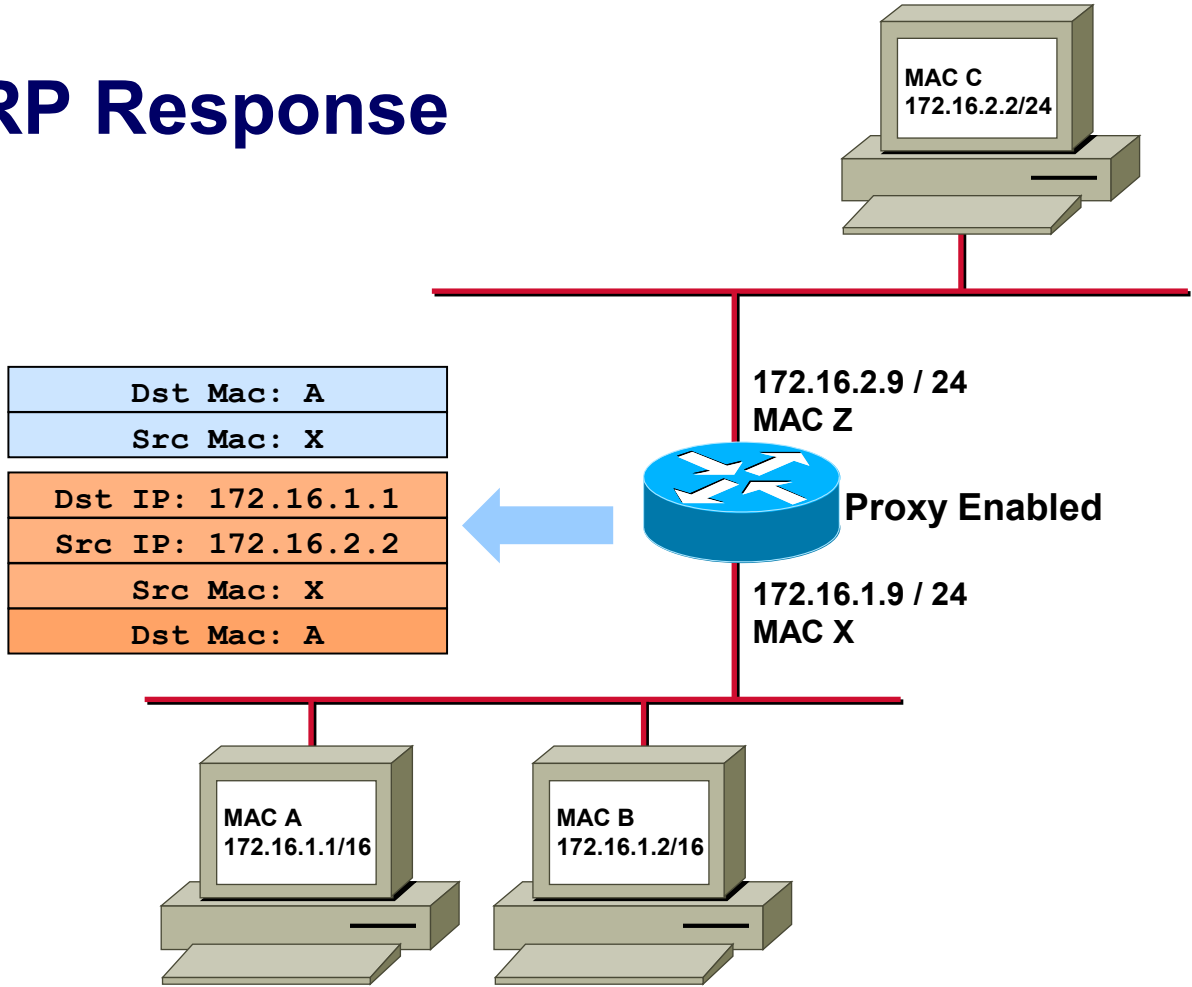

Proxy ARP Request

Proxy ARP (4)

Proxy ARP Response

Rules (1)

- **Proxy ARP only allowed to hide **subnets** – *not networks* !**
 - ◆ **Proxy ARP GW should not be used to bypass normal GWs**
- **Multiple Proxy ARP GWs**
 - ◆ **Requesting host will use the first ARP response it receives**
 - ◆ **Simple load balancing service**

Rules (2)

- **Proxy ARP GWs must not reply if the destination is reachable through the same interface**
 - ◆ **Either destination is in same segment**
 - ◆ **Or another Proxy ARP GW will reply, knowing a better route**

Disadvantages

- **Much ARP traffic**
 - ◆ Forwarded by bridges! (Broadcasts)
- **Hosts need larger ARP caches**
- **Address spoofing possible**
 - ◆ Station claims to be another station

ICMP

- **If network cannot deliver packets the sender must be informed somehow !**
 - ◆ **Reasons: no route, TTL expired, ...**
- **ICMP enhances network reliability and performance by carrying error and diagnostic messages**
- **ICMP must be supported by every IP station**
 - ◆ **Implementation differences!**

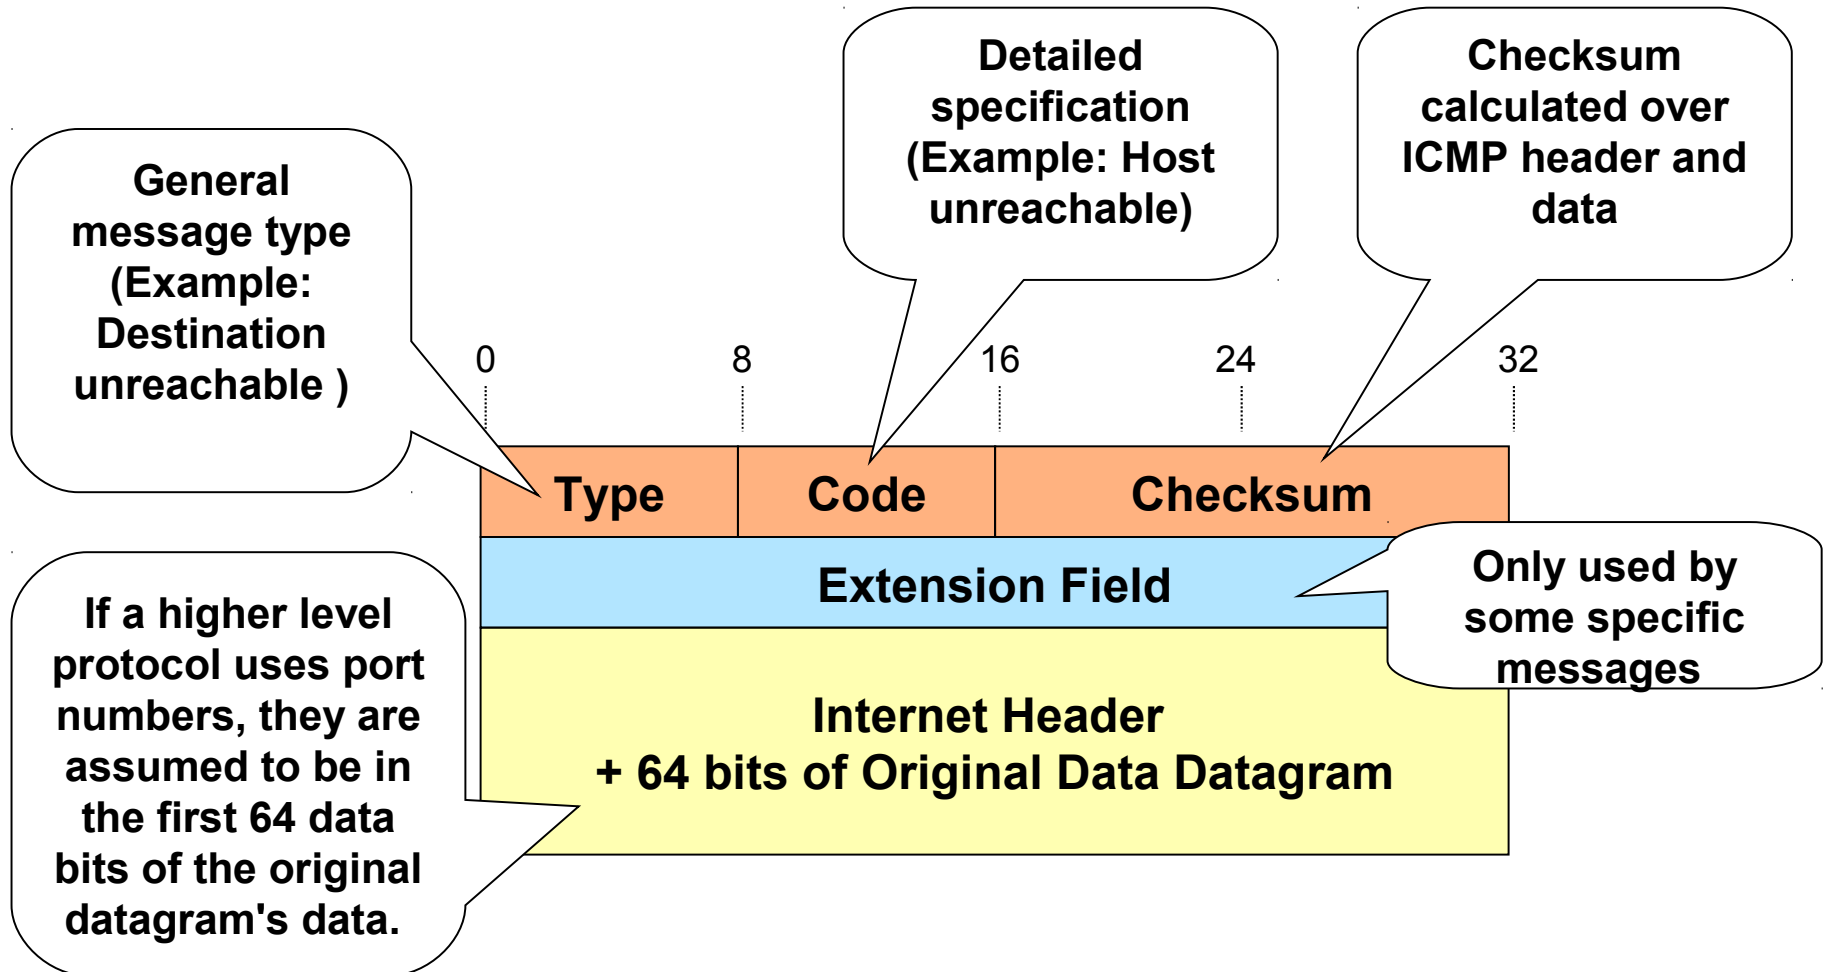

- Any station (host or router) detecting transmission problems sends ICMP error message back to the originator
- **ICMP gives feedback**
- ICMP messages are carried within IP packets
 - ◆ Protocol field = 1
 - ◆ ICMP header and code in the IP data area

- If a IP packet carrying an ICMP message cannot be delivered
 - ◆ No additional ICMP error message is generated to avoid an ICMP avalanche
 - ◆ **"ICMP must not invoke ICMP"**
- Exception: PING command
 - ◆ Echo request and echo response
 - ◆ Microsoft's tracert expects "TTL expired" upon "Echo request"

ICMP Message Format

Type Field Values

- (0)** - Echo reply ("PING")
- (3)** - Destination Unreachable
- (4)** - Source Quench (decrease data rate of sender)
- (5)** - Redirect (use different router)
- (8)** - Echo Request ("PING")
- (11)** - Time Exceeded (TTL = 0 or reassembly timer expired)
- (12)** - Parameter Problem (IP header)
- (13)** - Time Stamp Request
- (14)** - Time Stamp Reply
- (15/16)** - Information Request/Reply (finding the Net-ID of the network; e.g. SLIP)
- (17/18)** - Address Mask Request/Reply

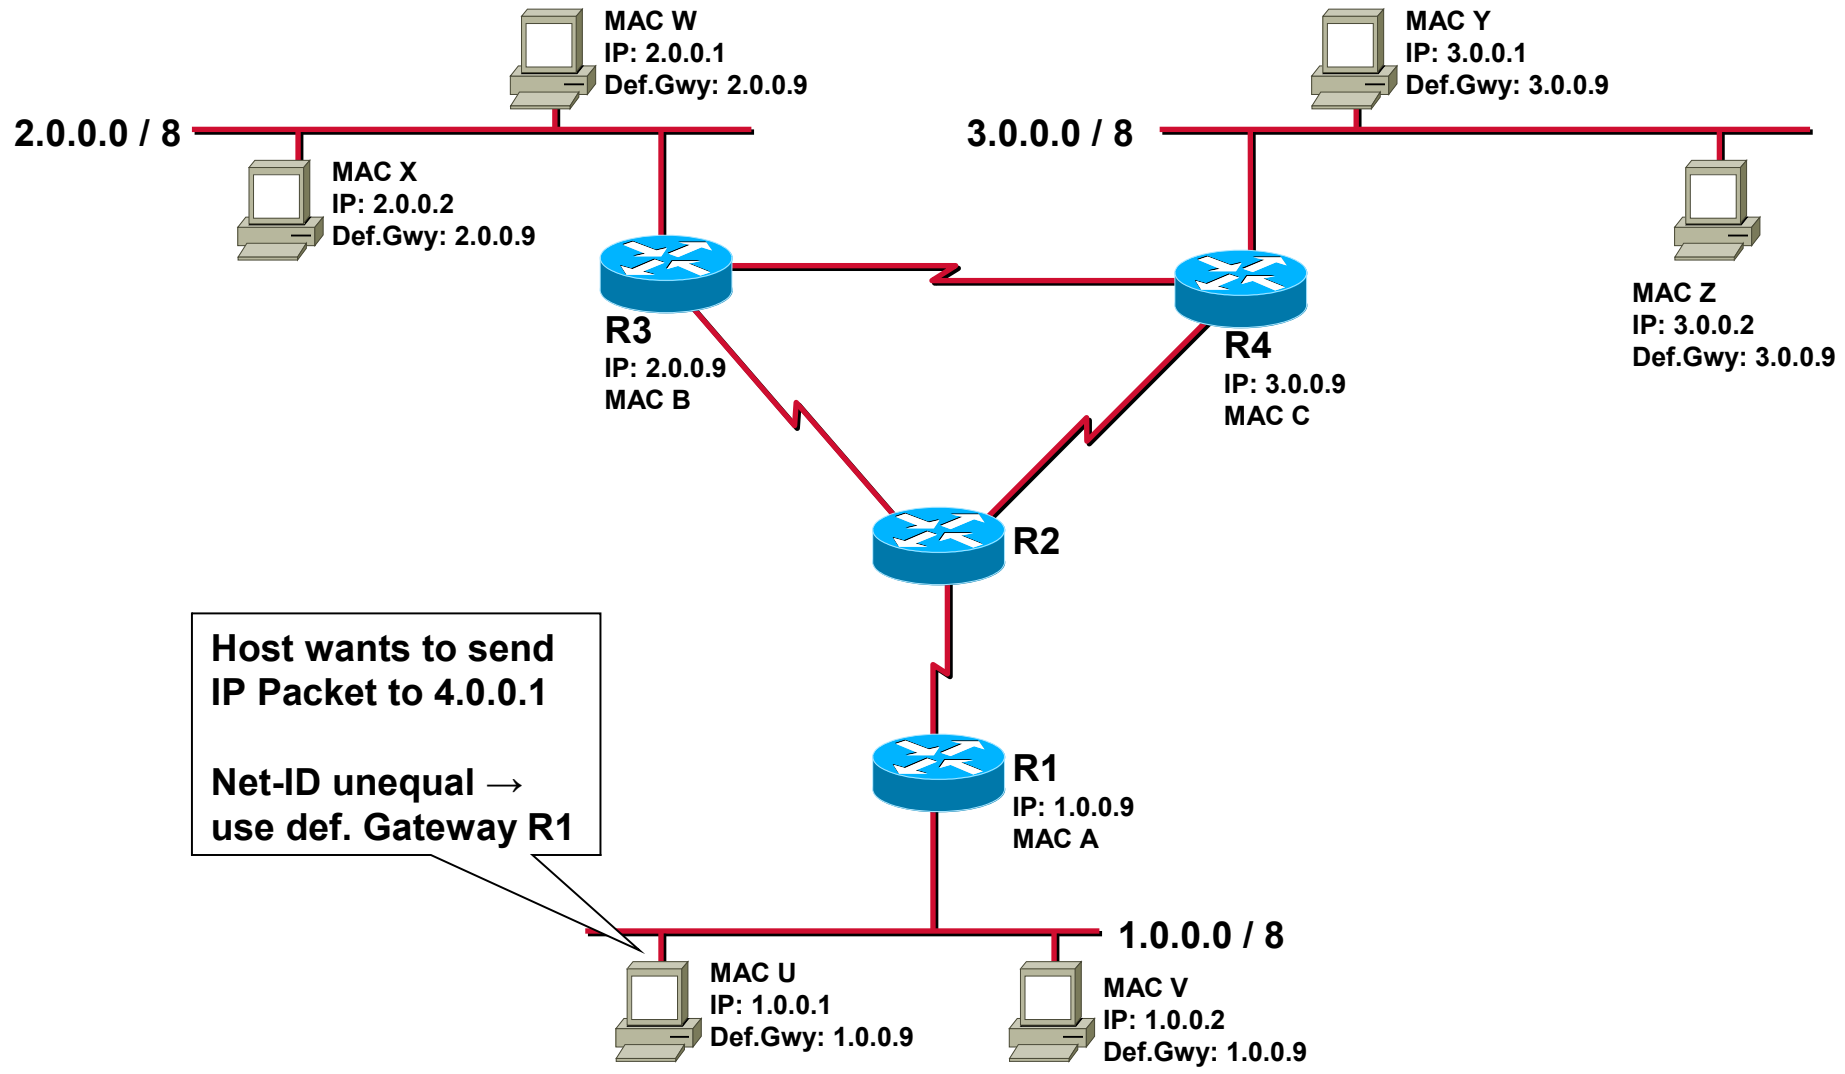

Example: Codes for Type 3

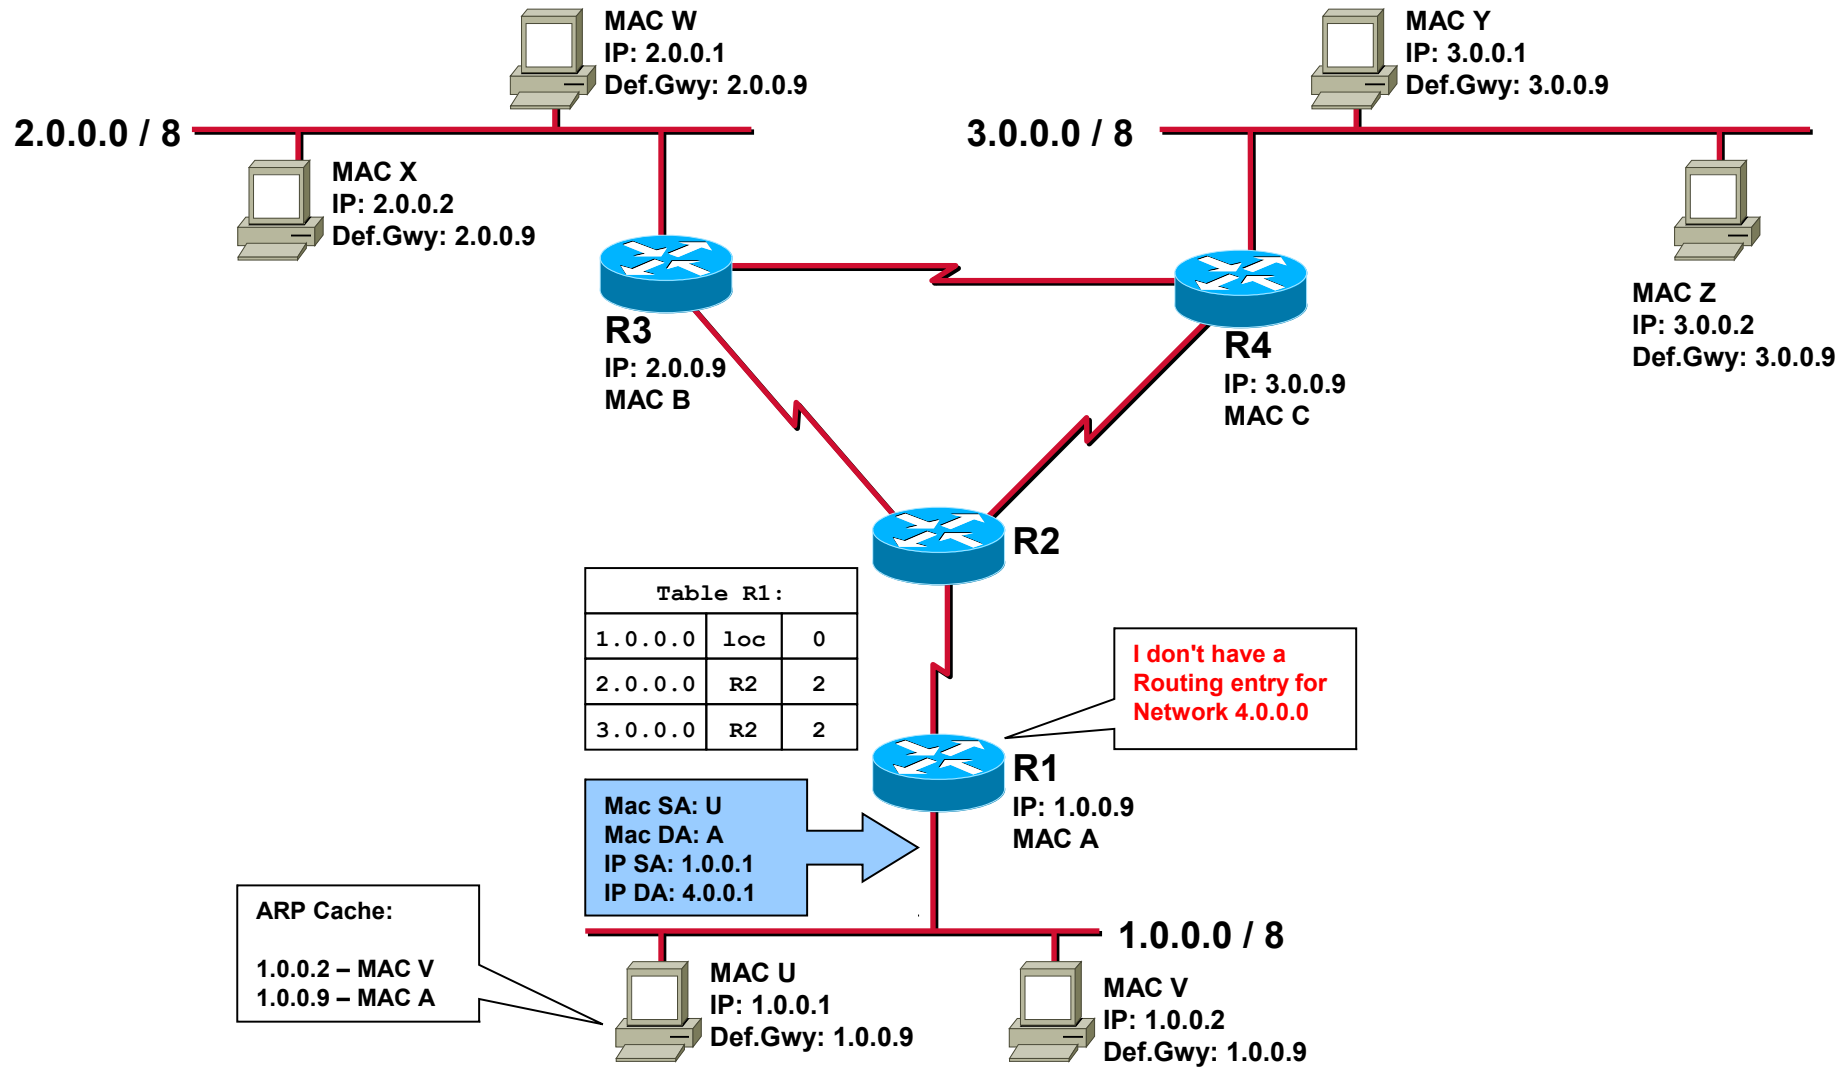

- (0) - Network unreachable: no path to network known or network down; generated by intermediate or far-end router.**
- (1) - Host unreachable: Host-ID can't be resolved or host not responding; generated by far-end router.**
- (2) - Protocol unreachable: protocol specified in IP header not available; generated by end system.**
- (3) - Port unreachable: port (service) specified in layer 4 not available; generated by end system.**
- (4) - Fragmentation needed and do not fragment bit set: DF bit =1 but the packet is too big for the network (MTU); generated by router.**
- (5) - Source route failed: Path in IP Options couldn't be followed; generated by intermediate or far-end router.**

IP Forwarding und ICMP(2)

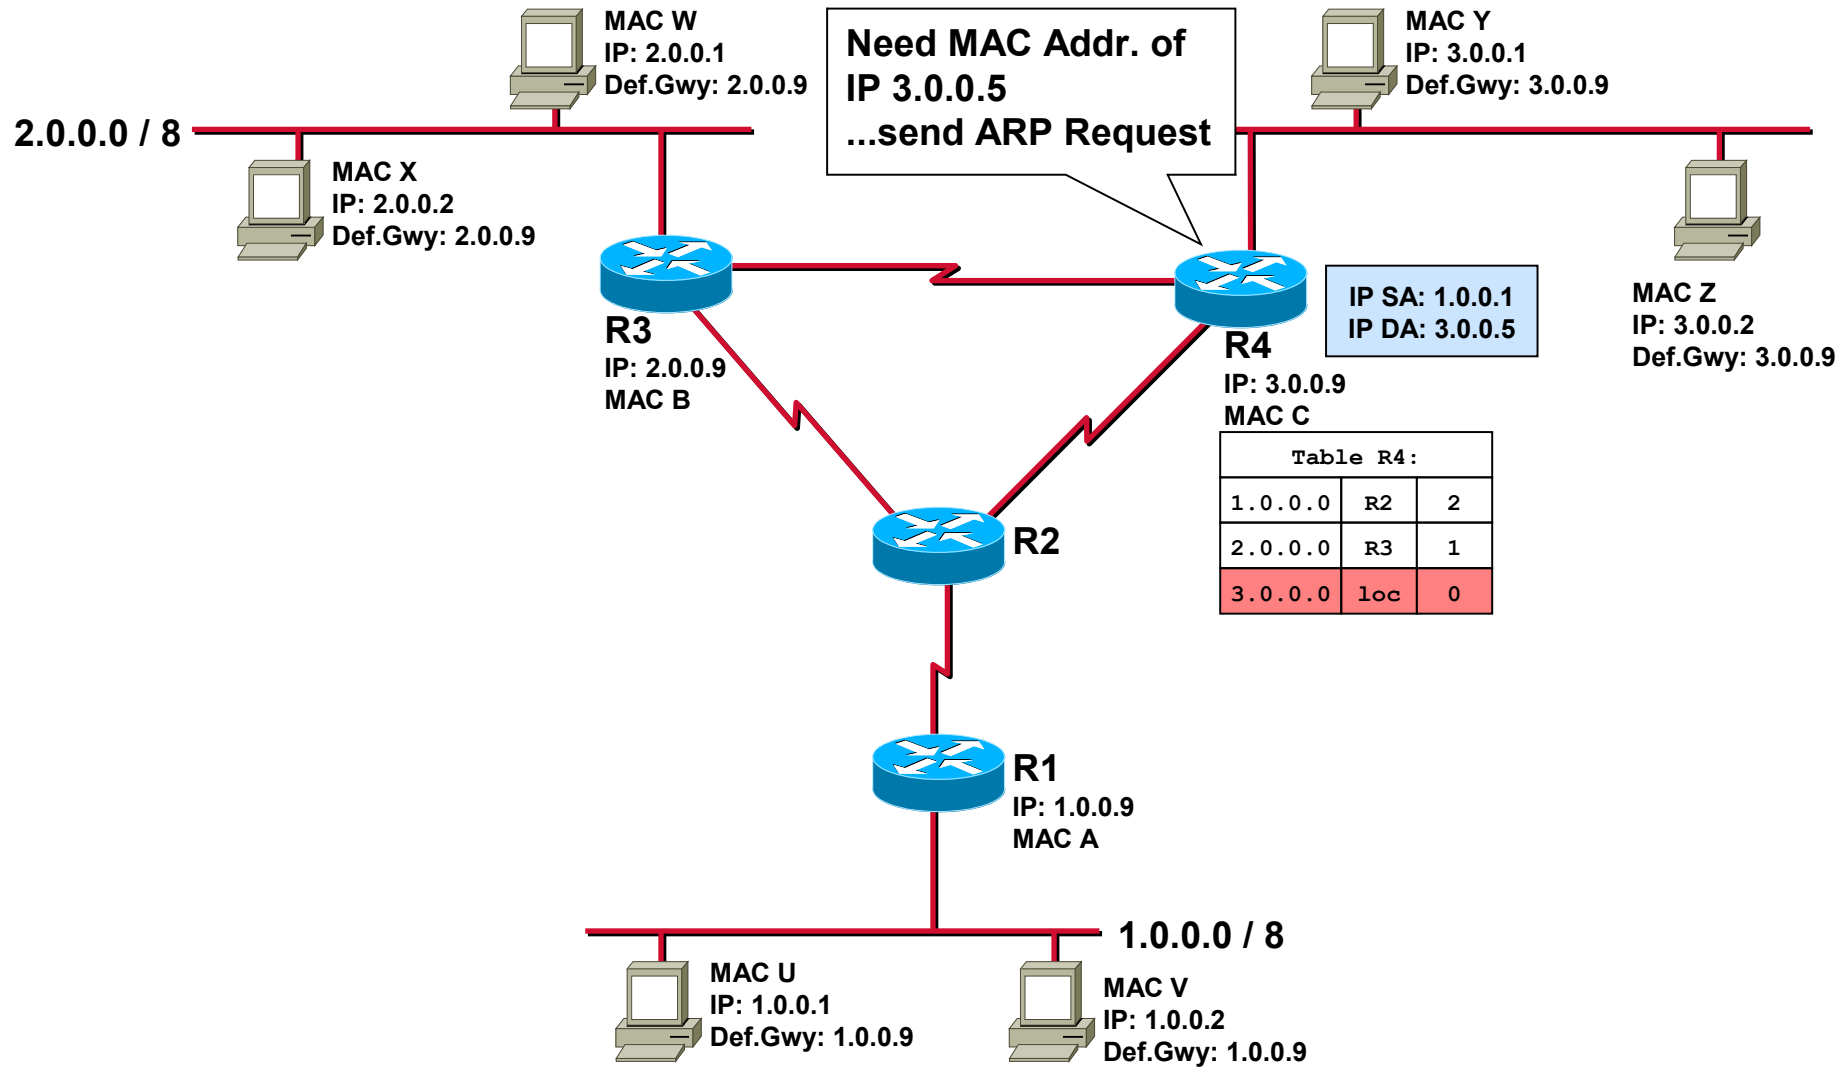

IP Forwarding und ICMP(2)

ICMP Redirect

- The interface on which the packet comes into the router is the same interface on which the packet gets routed out
- The subnet/network of the source IP address is the same subnet/network of the next-hop IP address of the routed packet
- The datagram is **not source-routed**
- The kernel is configured to send redirects

- **On Layer 3, IP-Addresses are used to route packets**
 - ◆ On Layer 2 different addresses are used (e.g. MAC-Address)
 - ◆ Mapping/Resolution needed → ARP
- **ARP is mostly dynamic (static entries are possible)**
- **The other way round: RARP (BootP, DHCP)**
- **ICMP is used to inform the originating IP-Host about what happend with its IP Packet**
 - ◆ IP Stacks do not neccesarily listen to ICMP message
 - ◆ Could be one way to implement flow-control (ICMP - source quench)

- **Why is ARP not needed on serial lines?**
- **Why are ARP-Cache entries timing out?**
- **Why should you use DHCP instead of RARP?**
- **What happens if a router discards an ICMP message?**
- **Ever heard of "Inverse ARP"?**
